cultured plant cells; (b) homogenizing the plant, plant derived tissue or cultured plant cells, so as to bring into contact the fusion protein with a cellulosic matter of the plant, plant derived tissue or cultured plant cells, to thereby effect affinity binding of the fusion protein via the cellulose binding peptide to the cellulosic matter, thereby obtaining a fusion protein cellulosic matter complex; and (c) isolating the fusion protein cellulosic matter complex.

PROCESS OF EXPRESSING AND ISOLATING RECOMBINANT
PROTEINS AND RECOMBINANT PROTEIN PRODUCTS FROM
PLANTS, PLANT DERIVED TISSUES OR CULTURED PLANT CELLS

5 FIELD AND BACKGROUND OF THE INVENTION

The present invention relates to a process of expressing and isolating recombinant proteins and recombinant protein products from plants, plant derived tissue or cultured plant cells, which process exploits (i) the high affinity between cellulose binding peptides and cellulose; (ii) the inherent
10 abundance of cellulose in *planta*; and/or (iii) the simplicity associated with cellulose isolation from plants, plant derived tissue and cultured plant cells.

More particularly, the present invention relates to a process expressing and isolating recombinant proteins and recombinant protein products from plants, plant derived tissue or cultured plant cells, which
15 process employs the expression of a fusion protein including a recombinant protein and a cellulose binding peptide fused thereto, plant homogenization, isolation of a fusion protein cellulosic matter complex and optional subsequent isolation of the fusion protein and/or the recombinant protein from the complex. The present invention further relates to nucleic acid
20 molecules and to genetically modified or viral infected plants or plant cells which are useful while implementing the process, and further to a novel composition of matter which results from the process.

Citation or identification of any reference in this section or in any other section of this application shall not be construed as an admission that
25 such reference is available as prior art to the present invention.

With the advent of recombinant technology, techniques for the genetic transformation of various host organisms, such as bacteria, yeasts, fungi, plants and animals, for the purposes of producing specific proteins through the expression of heterologous or foreign genes have been
30 extensively developed.

Using these recombinant techniques and hosts, numerous commercially important recombinant proteins (examples of which are included hereinbelow) have been expressed and purified. Expression and isolation of a protein of interest on a commercial scale, necessitate the
35 selection of a suitable expression host. This selection largely depends on the economics of production and purification, as well as the ability of the host to accomplish the post-translational modifications needed for full biological activity of the recombinant protein.

Much of the early work in biotechnology was directed toward the expression of recombinant or "heterologous" proteins in prokaryotes like *Escherichia coli* and *Bacillus subtilis* because of the relative ease of genetic manipulation, growth in batch culture and large-scale fermentation of prokaryotes.

Although *E. coli* can in certain cases perform some post translational modifications and events, such as, protein folding and disulfide bond formation, it cannot secrete proteins extracellularly nor can it glycosylate, gamma carboxylate, beta hydroxylate, acetylate or process pre- and pro-peptides. *B. subtilis* suffers from the same limitations as *E. coli* except that it is capable of extracellular secretion.

Furthermore, *E. coli* and other bacteria are pathogens and therefore, depending on the application, contaminants such as pyrogens and endotoxins expressed along with the recombinant protein must be removed. In addition, extensive post-purification chemical and enzymatic treatments (e.g., to refold the protein into an active form) are sometimes required in order to obtain a biologically active protein.

Because proteins are not secreted from prokaryotes like *E. coli*, bacterial cells must be disrupted for product recovery. The subsequent release of bacterial contaminants and other proteins make product purification more difficult and expensive. Because purification accounts for up to 90 % of the total cost of producing recombinant proteins in bacteria, proteins like Insulin can cost several thousand dollars per gram when recombinantly produced in, and subsequently isolated from, *E. coli*.

Because of the many limitations associated with prokaryotic hosts, the biotechnology industry has looked for eukaryotic host cultures such as, yeast, fungi, insect cells, and mammalian cell tissue culture, to properly and efficiently express recombinant proteins.

For most of the proteins requiring extensive post-translational modifications for therapeutic and/or functional activity, mammalian cell culture is the most common alternative to *E. coli*. Although mammalian cells are capable of correctly folding and glycosylating bioactive proteins, the quality and extent of glycosylation can vary with different culture conditions among the same host cells. Furthermore, mammalian culture has extremely high fermentation costs (60-80% of total production expense), requires expensive media, and poses safety concerns from potential contamination by viruses and other pathogens. Yields are generally low and

in the range of 0.5-1.5% of cellular protein, or micrograms per liter (up to 300-400 milligrams per liter).

Yeast, other fungi, and insect cells are currently being used as alternatives to mammalian cell culture. Yeast, however, produces
5 incorrectly glycosylated proteins that have excessive mannose residues and are generally limited in eukaryotic processing. Further, although the baculovirus insect cell system can produce high levels of glycosylated proteins, these are typically not secreted, making purification complex and expensive. Fungi represent the best current system for high-volume, low-
10 cost production of recombinant proteins, but they are not capable of expressing many target proteins.

In addition, eukaryotic cultures, require the maintenance of suitable conditions for efficient commercially viable expression of proteins. As such, the ambient temperature, pH value and aeration level of such cultures
15 need to be carefully controlled, while nutrients must be added to the culture medium in carefully regulated doses and waste products removed. In addition, rigorous aseptic practices must be observed in order to avoid contamination by extraneous microbes. Such cultures are thus normally grown in sophisticated fermentors or bioreactors which are housed in
20 expensively maintained factories. Such overheads are reflected in the high price of the recombinant protein end-products.

To a lesser extent, animals have also been utilized for the production of recombinant proteins. Although large amounts of protein can be produced and relatively easily recovered from such animals (e.g., proteins
25 specifically produced in mammary glands and secreted with the milk), production in such host is limited to the expression of proteins which do not interfere with the host physiology. In addition, transgenic animals are subject to lengthy lead times to develop herds with stable genetics, high operating costs, contamination by animal viruses and a relatively slow rate
30 of biomass generation substantially prolonging the time period following which recovery of commercial amounts of the protein can be effected.

The biochemical, technical and economic limitations on existing prokaryotic and eukaryotic expression systems has created substantial interest in developing new expression systems for the production of
35 recombinant proteins.

Plants represent the most likely alternative to existing expression systems. With the availability and on going development of plant

transformation techniques, most commercially important plant species can now be genetically modified to express a variety of recombinant proteins.

Such transformation techniques include, for example, the *Agrobacterium* vector system, which involves infection of the plant tissue with a bacterium (*Agrobacterium*) into which the foreign gene has been inserted. A number of methods for transforming plant cells with *Agrobacterium* are well known (Klee *et al.*, Annu. Rev. Plant Physiol. (1987) 38:467-486; Schell and Vasil Academic Publishers, San Diego, Calif. (1989) p. 2-25; and Gatenby (1989) in Plant Biotechnology, eds. Kung, S. and Arntzen, C. J., Butterworth Publishers, Boston, Mass. p. 93-112).

The biolistic or particle gun method, which permits genetic material to be delivered directly into intact cells or tissues by bombarding regeneratable tissues, such as meristems or embryogenic callus, with DNA-coated microparticles has contributed to plant transformation simplicity and efficiency. The microparticles penetrate the plant cells and act as inert carriers of a genetic material to be introduced therein. Microprojectile bombardment of embryogenic suspension cultures has proven successful for the production of transgenic plants of a variety of species. Various parameters that influence DNA delivery by particle bombardment have been defined (Klein *et al.*, Bio/Technology (1998) 6:559-563; McCabe *et al.*, Bio/Technology (1998) 6:923-926; and Sanford, Physiol. Plant. (1990) 79:206-209).

Micropipette systems are also used for the delivery of foreign DNA into plants via microinjection (Neuhaus *et al.*, Theor. Appl. Genet. (1987) 75:30-36; and Neuhaus and Spangenberg, Physiol. Plant. (1990) 79:213-217).

Other techniques developed to introduce foreign genes into plants include direct DNA uptake by plant tissue, or plant cell protoplasts (Schell and Vasil (1987) Academic Publishers, San Diego, Calif. p. 52-68; and Toriyama *et al.*, Bio/Technology (1988) 6:1072-1074) or by germinating pollen (Chapman, Mantell and Daniels (1985) W. Longman, London, p. 197-209; and Ohta, Proc. Natl. Acad. Sci. USA (1986) 83:715-719).

DNA uptake induced by brief electric shock of plant cells has also been described (Zhang *et al.*, Plant. Cell. Rep. (1988) 7:379-384 and Fromm *et al.*, Nature (1986) 319:791-793).

In addition, virus mediated plant transformation has also been extensively described. Transformation of plants using plant viruses is

described, for example, in U.S. Pat. No. 4,855,237 (BGV), EP-A 67,553 (TMV), Japanese Published Application No. 63-14693, EPA 194,809, EPA 278,667, and Gluzman *et al.*, (1988) Communications in Molecular Biology: Viral Vectors, Cold Spring Harbor Laboratory, New York, pp. 172-189. Pseudovirus particles for use in expressing foreign DNA in many hosts, including plants, have also been described, for reference, see, for example WO 87/06261.

The production of recombinant proteins and peptides in plants has been investigated using a variety of approaches including transcriptional fusions using a strong constitutive plant promoter (e.g., from cauliflower mosaic virus, Sijmons *et al.*, Bio/Technology (1990) 8:217-221); transcriptional fusions with organ specific promoter sequences (Radke *et al.*, Theoret. Appl. Genet. (1988) 75:685-694); and translational fusions which require subsequent cleavage of a recombinant protein (Vanderkerckove *et al.*, Bio/Technology (1989) 7:929-932).

The application of such genetic transformation techniques has allowed the incorporation of a variety of important genetic traits for crop improvement and also for the biotechnological production of extractable, valuable, foreign proteins including enzymes, vaccine proteins and antibodies.

Foreign proteins that have been successfully expressed in plant cells include proteins from bacteria (Fraley *et al.* Proc. Natl. Acad. Sci. U.S.A. (1993) 80:4803-4807), animals (Misra and Gedamu, Theor. Appl. Genet. (1989) 78:161-168), fungi and other plant species (Fraley *et al.* Proc. Natl. Acad. Sci. U.S.A. (1983) 80:4803-4807). Some proteins, predominantly markers of DNA integration, have been expressed in specific cells and tissues including seeds (Sen Gupta-Gopalan *et al.* Proc. Natl. Acad. Sci. U.S.A. (1985) 82:3320-3324; Radke *et al.* Theor. Appl. Genet. (1988) 75:685-694).

Due to the advantageous economics of field-grown crops, the ability to synthesize proteins in storage organs like tubers, seeds, fruits and leaves and the ability of plants to perform many of the post-translational modifications previously described, several plant expression systems are currently investigated for potential as highly effective and economically feasible systems for the production of recombinant proteins.

Since highly expressive systems such as the ubiquitin fusion system described in U.S. Pat. No. 5,773,705 have been demonstrated, a major hurdle to an effective plant expression system resides with the relatively

complicated purification procedures necessary in order to purify the recombinant protein.

As such, alternative expression approaches have been undertaken in an effort to simplify the purification procedure of the recombinant protein from the plant cells.

One such system focuses on the use of seed-storage protein promoters as a means of deriving seed-specific expression. Using such a system, Vanderkerckove *et al.*, (Bio/Technol. (1989) 7:929-932) expressed the peptide Leu-enkephalin in seeds of *Arabidopsis thaliana* and *Brassica napus*. The level of expression of this peptide was quite low and it appeared that expression of this peptide was limited to endosperm tissue.

Another system utilizing seeds as an expression host is disclosed in U.S. Pat. No. 5,888,789. This system provides for the secretion of heterologous protein by malting of monocot plant seeds. The heterologous genes are expressed during germination of the seeds and isolated from a malt.

U.S. Pat. No. 5,580,768 describes a method of producing a genetically transformed fluid-producing plant. The genetically transformed plant which can be for example, a rubber secreting (*Hevea*) plant is capable of expressing the target product in the fluid that it produces which in this case is latex.

U.S. Pat No. 5,650,554 describes the use of a class of genes called oil body protein genes, that have unique features, allowing the production of recombinant proteins that can be easily separated from other host cell components.

Many additional expression systems have been described utilizing specific targeting or directing of recombinant proteins to specific plant tissues.

Although systems which target or direct recombinant protein production to specific tissues allow for easier recombinant protein isolation such systems are typically limited in the effective host range and/or the amounts of recombinant proteins produced since such systems fail to exploit the entire plant biomass.

A novel approach for simplifying the purification of recombinant enzymes from plant host cells is disclosed in U.S. Pat. No. 5,474,925 which describes an expression construct utilizing a signal peptide translationally fused to a recombinant enzyme which targets the enzyme to the cellulose matrix of the cell wall. This enables the isolation of the

enzyme along with the easily recoverable cellulose matrix. This system is utilized for the localized expression of commercially important enzymes in cotton fibers. According to this system, the expressed enzymes are recovered along with the cellulosic matter of the fibers. The enzyme-cellulose matrix recovered, is directly utilized for commercial enzymatic processes.

Although this system presents a simple means with which a recombinant protein can be expressed and isolated, it is limited to the production of enzymes in cotton fibers of the cotton plant.

Furthermore, a major hurdle encountered when expressing cellulose targeted proteins within a plant is the interference of the expressed products in the natural formation of the cell wall, which typically results in growth arrest of the plant growth. Although this hurdle can be overcome by, for example, targeting the protein to specific plant tissue as is the case for U.S. Pat. No. 5,474,925, this targeting severely limits the expressing biomass and as such the quantity of the expressed protein. In addition, targeting the expression to a specific plant tissue also limits the number of plant species which can be effectively utilized for such an expression.

There is thus a widely recognized need for, and it would be highly advantageous to have, a plant expression system and method which provide high level of expression of a recombinant protein and which allow simple and effective recovery of the expressed recombinant protein devoid of the above limitations.

SUMMARY OF THE INVENTION

According to one aspect of the present invention there is provided a process of expressing a recombinant protein in a plant and of isolating the recombinant protein from the plant, the process comprising the steps of (a) providing a plant, a plant derived tissue or cultured plant cells expressing a fusion protein including the recombinant protein and a cellulose binding peptide being fused thereto, the fusion protein being compartmentalized within cells of the plant, plant derived tissue or cultured plant cells, so as to be sequestered from cell walls of the cells of the plant, plant derived tissue or cultured plant cells; (b) homogenizing the plant, plant derived tissue or cultured plant cells, so as to bring into contact the fusion protein with a cellulosic matter of the plant, plant derived tissue or cultured plant cells, to thereby effect affinity binding of the fusion protein via the cellulose binding peptide to the cellulosic matter, thereby obtaining a fusion protein cellulosic

matter complex; and (c) isolating the fusion protein cellulosic matter complex.

According to further features in preferred embodiments of the invention described below, the process further comprising the steps of
5 washing the fusion protein cellulosic matter complex, thereby removing endogenous plant proteins and other plant material therefrom and collecting the fusion protein cellulosic matter complex as a final product of the process.

According to still further features in the described preferred
10 embodiments the process further comprising the steps of washing the fusion protein cellulosic matter complex, thereby removing endogenous plant proteins and other plant material therefrom, exposing the fusion protein cellulosic matter complex to conditions effective in dissociating the fusion protein from the cellulosic matter; and isolating the fusion protein, thereby
15 obtaining an isolated fusion protein.

According to still further features in the described preferred embodiments the process further comprising the steps of exposing the isolated fusion protein to conditions effective in digesting the fusion protein so as to release the recombinant protein therefrom, thereby obtaining a
20 released recombinant protein and isolating the released recombinant protein.

According to still further features in the described preferred embodiments the process further comprising the steps of washing the fusion protein cellulosic matter complex, thereby removing endogenous plant proteins and other plant material therefrom, exposing the fusion protein
25 cellulosic matter complex to conditions effective in digesting the fusion protein so as to release the recombinant protein therefrom, thereby obtaining a released recombinant protein, and isolating the released recombinant protein.

According to still further features in the described preferred
30 embodiments, the conditions effective in dissociating the fusion protein from the cellulosic matter are selected from the group consisting of basic conditions, denaturative conditions and affinity displacement conditions.

According to still further features in the described preferred embodiments, the conditions effective in digesting the fusion protein so as
35 to release the recombinant protein therefrom are selected from the group consisting of proteolysis effected via a protease and proteolysis effected under predetermined cis or trans conditions for digesting a controllable intervening protein sequence.

According to another aspect of the present invention there is provided a genetically modified or viral infected plant or cultured plant cells expressing a fusion protein including a recombinant protein and a cellulose binding peptide

5 According to further features in preferred embodiments of the invention described below, the fusion protein is compartmentalized within cells of the plant or cultured plant cells, so as to be sequestered from cell walls of the cells of the plant or cultured plant cells.

10 According to still further features in the described preferred embodiments the fusion protein is compartmentalized within a cellular compartment selected from the group consisting of cytoplasm, endoplasmic reticulum, golgi apparatus, oil bodies, starch bodies, chloroplastids, chloroplasts, chromoplastids, chromoplasts, vacuole, lysosomes, mitochondria, and nucleus.

15 According to still further features in the described preferred embodiments expression of the fusion protein is under a control of a constitutive or tissue specific plant promoter.

20 According to still further features in the described preferred embodiments the fusion protein includes a recombinant protein and a cellulose binding peptide separated therebetween via a unique amino acid sequence recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein sequence.

25 According to yet another aspect of the present invention there is provided a composition of matter comprising (a) a plant derived cellulosic matter; and (b) a fusion protein including a recombinant protein and a cellulose binding peptide separated therebetween via a unique amino acid sequence recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein
30 sequence, the fusion protein being complexed to the plant derived cellulosic matter by affinity binding via the cellulose binding peptide.

35 According to still another aspect of the present invention there is provided a nucleic acid molecule comprising (a) a promoter sequence for directing protein expression in plant cells; (b) a heterologous nucleic acid sequence including (i) a first sequence encoding a cellulose binding peptide; (ii) a second sequence encoding a recombinant protein, wherein the first and second sequences are joined together in frame; optionally (iii) a third sequence encoding a signal peptide for directing a protein to a cellular

compartiment, the third sequence being upstream and in frame with the first and second sequences; and/or optionally (iv) a fourth sequence encoding a unique amino acid sequence being recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein sequence, the fourth sequence being between and in frame with the first and second sequences, wherein, the heterologous nucleic acid sequence being down stream the promoter sequence, such that expression of the heterologous nucleic acid sequence is effectable by the promoter sequence.

According to further features in preferred embodiments of the invention described below, the nucleic acid molecule further comprising a sequence element selected from the group consisting of an origin of replication for propagation in bacterial cells, at least one sequence element for integration into a plant's genome, a polyadenylation recognition sequence, a transcription termination signal, a sequence encoding a translation start site, a sequence encoding a translation stop site, plant RNA virus derived sequences, plant DNA virus derived sequences, tumor inducing (Ti) plasmid derived sequences, and a transposable element derived sequence.

The present invention successfully addresses the shortcomings of the presently known configurations by providing a novel process of expressing and isolating recombinant proteins and recombinant protein products from plants, plant derived tissue or cultured plant cells, which process exploits (i) the high affinity between cellulose binding peptides and cellulose; (ii) the inherent abundance of cellulose in *planta*; and (iii) the simplicity associated with cellulose isolation from plants, plant derived tissue and/or cultured plant cells.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention is herein described, by way of example only, with reference to the accompanying drawings. With specific reference now to the drawings in detail, it is stressed that the particulars shown are by way of example and for purposes of illustrative discussion of the preferred embodiments of the present invention only, and are presented in the cause of providing what is believed to be the most useful and readily understood description of the principles and conceptual aspects of the invention. In this regard, no attempt is made to show structural details of the invention in more detail than is necessary for a fundamental understanding of the

invention, the description taken with the drawings making apparent to those skilled in the art how the several forms of the invention may be embodied in practice.

In the drawings:

5 FIG. 1 is a process flow chart demonstrating the process according to the present invention.

FIGs. 2a-b are nucleotide (2a) and restriction maps (2b) of the insert into the pUC19-cell1-ProtL-cexNG vector constructed in accordance with the teachings of the present invention.

10 FIGs. 3a-b are nucleotide (3a) and restriction maps (3b) of the insert into the pBS-Sig-cex-Fx-HDEL vector constructed in accordance with the teachings of the present invention.

FIGs. 4a-b are nucleotide (4a) and restriction maps (4b) of the insert into the pBS-Sig-Tma-Fx-HDEL vector constructed in accordance with the teachings of the present invention.

15 FIG. 5 is a flow chart diagram depicting the step involved in the analysis of the transgenic plant material produced according to the teachings of the present invention.

FIGs. 9a-b are immunoblot images of proteins extracted from ProtL-cexNG transformants. The extracted proteins were separated on SDS-PAGE, blotted, and reacted with anti CBDcex antibody(6a) or mouse IgG (6b) as is further described in Example 2. M - MWM, a -a WT plant cell wall fraction, b - transformant line 2 cell wall fraction, c - WT cellulose fraction (exogenous), d - transformant line 2 cellulose fraction.

35 FIGs. 10a-b are immunoblot images of proteins extracted from CBDcex-fx transformants. The extracted proteins were separated on SDS-PAGE, blotted, and reacted with anti-Fx (7a) or anti-CBDcex (7b) antibodies as is further described in Example 2. C - positive control, M - MWM, wt - WT plant line, 5-24 - transformant plant lines.

FIGs. 11a-d are immunoblot images of proteins extracted from CDBTma-fx transformants. The extracted proteins were separated on SDS-PAGE, blotted, and reacted with anti-Fx antibodies as is further described in Example 2. Figures 11a and 11c represent proteins extracted from the cellulose fraction, while Figures 11b and 11d represent proteins extracted from the wall fraction. C - positive control, M - MWM, wt - WT plant line, 2-19 - transformant plant lines.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention is of a process which can be used for expressing and isolating recombinant proteins and recombinant protein products from plants, plant derived tissue or cultured plant cells. The present invention is further of nucleic acid molecules and genetically modified or viral infected plants or plant cells which are useful while implementing the process, and further of a novel composition of matter which results from the process. Specifically, the present invention can be used to obtain large quantities of the recombinant proteins and the recombinant protein products in a simple and cost effective manner, since the process according to the present invention exploits (i) the high affinity between cellulose binding peptides and cellulose; (ii) the inherent abundance of cellulose in *planta*; and (iii) the simplicity associated with cellulose isolation from plants, plant derived tissue and/or cultured plant cells.

The principles and operation of a process according to the present invention may be better understood with reference to the drawings and accompanying descriptions.

Before explaining at least one embodiment of the invention in detail, it is to be understood that the invention is not limited in its application to the details of construction and the arrangement of the components set forth in the following description or illustrated in the drawings. The invention is capable of other embodiments or of being practiced or carried out in various ways. Also, it is to be understood that the phraseology and terminology employed herein is for the purpose of description and should not be regarded as limiting.

Process:

Referring now to the drawings, Figure 1 is a flow chart illustrating the process according to the teachings of the present invention.

The process according to the present invention is directed at expressing a recombinant protein in a plant and further at isolating the recombinant protein from the plant. The process according to the present invention is effected by first providing a plant, a plant derived tissue or
5 cultured plant cells (which are referred to herein below individually and collectively as "plant material") 10 expressing a fusion protein which includes the recombinant protein and a cellulose binding peptide fused thereto. The fusion protein is compartmentalized within cells of the plant material, so as to be sequestered from cell walls of the cells of the plant
10 material. As used herein in the specification and in the claims section that follows, the phrase "cultured plant cells" includes both non-differentiated plant cell cultures and some what more differentiated callus cultures.

Compartmentalizing and thereby sequestering the fusion protein from the cell walls is an essential feature of the present invention because
15 high levels of expressed cellulose binding peptide associated with plant cell walls inhibit plant growth to a great extent. See to this effect U.S. Pat. applications Nos. 09/006,632; 09/006,636; and PCT/IL98/00345 (WO 99/07830).

When sufficient expression has been detected by sampling and
20 testing the plant material as further detailed hereinunder, the plant material is homogenized 12 so as to bring into contact the fusion protein with a cellulosic matter of the plant material, to thereby effect affinity binding 14 of the fusion protein via the cellulose binding peptide to the cellulosic matter, thereby obtaining a fusion protein cellulosic matter complex.
25 Conditions such as, but not limited to, temperature, pH, salt concentration, time and the like are preferably set so as to allow maximal binding. Such conditions are well know to the skilled artisan and can be experimentally modified to best suit a specific application. Sampling and testing can be employed to monitor the binding process, as further detailed hereinunder.

30 When sufficient binding has occurred the fusion protein cellulosic matter complex is collected or isolated 16 by methods well known to the skilled artisan which method are traditionally employed for isolation of cellulosic matter from plant material. Thereafter, a wash step 18 is employed to remove unbound material, including, in particular, unbound
35 endogenous plant proteins, thereby isolating the fusion protein cellulosic matter complex. The wash step can be repeated one or several times with a single or several wash solutions, each of which can include in addition to water, buffers, salts, detergents and the like to efficiently effect the removal

of unbound matter from the fusion protein cellulosic matter complex. The wash step can be effected in solution using appropriate stirring, however, advantageously, the wash step is effected within a column into which the collected or isolated fusion protein cellulosic matter complex is packed and subsequently washed.

According to one embodiment of the present invention, and as indicated in Figure 1 by numeral 20, the fusion protein cellulosic matter complex is collected as a final product of the process. Such a final product can serve as a pack for affinity columns. In this case the recombinant protein is selected to have affinity to a ligand, which can then be affinity purified via a column packed with the fusion protein cellulosic matter complex, in a manner otherwise similar to that described in U.S. Pat. No. 5,474,925, which is incorporated herein by reference. One of the advantages of the process described herein over the teachings of U.S. Pat. No. 5,474,925 is that by sequestering the fusion protein from the cell walls one can achieve very high expression of the fusion protein as compared to the low expression levels practically enabled by U.S. Pat. No. 5,474,925, because no deleterious effect on plant growth is exerted. As a result, the specific activity of the fusion protein cellulosic matter complex formed according to the present invention, i.e., the number of fusion protein molecules per weight of cellulosic matter, is far superior. Further details relating to the effect of high cellulose binding peptide expression on plant development see also PCT/IL98/000345.

According to another embodiment of the present invention, as indicated by numeral 22, the final product of the process according to the present invention is the fusion protein itself 24. Thus, according to this embodiment of the present invention, conditions effective in dissociating the fusion protein from the cellulosic matter are used to effect such dissociation. The dissociated fusion protein is thereafter readily isolated by any conventional separation technique, such as, but not limited to, elution or size separation, such as differential filtration or centrifugation, thereby obtaining an isolated fusion protein. Conditions effective in dissociating the fusion protein from the cellulosic matter include, but are not limited to, basic conditions (e.g., 20 mM Tris pH 12) which are known to dissociate all cellulose binding peptides from cellulose, denaturative conditions, or affinity displacement conditions, e.g., using 200 nM glucose or cellobiose which are known in their ability to elute family IX cellulose binding domains (CBDs). Alternatively, a protein cleavage site can be inserted in the

cellulose binding peptide to facilitate the dissociation of the fusion protein by specific proteolysis, for example. See to this effect and to other uses of CBD-fusion proteins U.S. Pat. Nos. 5,719,044; 5,670,623; 5,856,021; 5,137,819; 5,202,247; 5,340,731; and 5,474,925; and U.S. Pat. applications
5 Nos. 08/788,621; and 08/788,622; EP 0 381 719 B1, and EP application No. 93907724.4. See also the teachings of U.S. Pat. No. 5,834,247, which is further described hereinunder.

As indicated by numeral 26, the fusion protein thus isolated can be exposed to conditions effective in digesting the fusion protein so as to
10 release the recombinant protein therefrom, thereby obtaining a released recombinant protein which can be thereafter isolated as a final product 28. Conditions effective in digesting the fusion protein so as to release the recombinant protein therefrom include, but are not limited to, proteolysis effected via a protease, such as, but not limited to, Factor Xa, enterokinase,
15 thrombin, trypsin, papain, pepsin, chemotrypsin and the like, or proteolysis effected via controllable intervening protein sequence (CIVPS) inserted into or adjacent the cellulose binding peptide, the CIVPS are capable of excision from or cleavage of the peptide under predetermined conditions in cis or in trans, e.g., increase in temperature, exposure to light, unblocking of amino
20 acid residues by dephosphorylation and treatment with chemical reagents or deglycosylation, examples include proteolysis effected under acidic conditions (HCl, e.g., to cleave between Asp and Pro) and proteolysis effected by a proteolysing reagent, such as CNBr to cleave downstream of Met, all as known in the art and/or as further described in U.S. Pat. No.
25 5,834,247, which is incorporated herein by reference.

Isolating final product 28 from other proteolytic products derived, for example, from the cellulose binding peptide, can be effected by any one of a number of protein isolation techniques well known to the skilled artisan, including, but not limited to, affinity separation via, for example, antibodies
30 bound to a solid support, size and/or charge based separation via gel electrophoresis or chromatography, and the like. Additional methods include, but are not limited to, fractionation, gel-filtration, ion-exchange, hydrophobic, and affinity chromatography, ultrafiltration and crystallization.

According to an alternative embodiment of the process of the present
35 invention, as indicated in Figure 1 by numeral 30, the washed fusion protein cellulose matter complex resulting from step 18 is exposed to conditions effective in digesting the fusion protein so as to release the recombinant protein therefrom, thereby obtaining a released recombinant protein. These

conditions are similar to those described with respect to step 26. The released recombinant protein is thereafter readily isolated by any conventional separation technique, such as, but not limited to, displacement or size separation, such as differential filtration or centrifugation, thereby
5 obtaining an isolated recombinant protein final product 32.

Cellulose binding peptides:

As used herein in the specification and in the claims section below, the phrase "cellulose binding peptide" includes peptides e.g., proteins and domains (portions) thereof, which are capable of, when expressed in plant
10 cells, affinity binding to a plant derived cellulosic matter following homogenization and cell rupture. The phrase thus includes, for example, peptides which were screened for their cellulose binding activity out of a library, such as a peptide library or a DNA library (e.g., a cDNA expression library or a display library) and the genes encoding such peptides isolated
15 and are expressible in plants. Yet, the phrase also includes peptides designed and engineered to be capable of binding to cellulose and/or units thereof.

Such peptides include amino acid sequences expressible in plants that are originally derived from a cellulose binding region of, e.g., a
20 cellulose binding protein (CBP) or a cellulose binding domain (CBD). The cellulose binding peptide according to the present invention can include any amino acid sequence expressible in plants which binds to a cellulose polymer. For example, the cellulose binding domain or protein can be derived from a cellulase, a binding domain of a cellulose binding protein or
25 a protein screened for, and isolated from, a peptide library, or a protein designed and engineered to be capable of binding to cellulose or to saccharide units thereof, and which is expressible in plants. The cellulose binding domain or protein can be naturally occurring or synthetic, as long as it is expressible in plants. Suitable polysaccharidases from which a
30 cellulose binding domain or protein expressible in plants may be obtained include β -1,4-glucanases. In a preferred embodiment, a cellulose binding domain or protein from a cellulase or scaffoldin is used. Typically, the amino acid sequence of the cellulose binding peptide expressed in plants according to the present invention is essentially lacking in the hydrolytic
35 activity of a polysaccharidase (e.g., cellulase, chitinase), but retains the cellulose binding activity. The amino acid sequence preferably has less than about 10 % of the hydrolytic activity of the native polysaccharidase; more preferably less than about 5 %, and most preferably less than about 1 % of

the hydrolytic activity of the native polysaccharidase, ideally no activity altogether.

The cellulose binding domain or protein can be obtained from a variety of sources, including enzymes and other proteins which bind to cellulose which find use in the subject invention.

In Table 4 below are listed those binding domains which bind to one or more soluble/insoluble polysaccharides including all binding domains with affinity for soluble glucans (α , β , and/or mixed linkages). The N1 cellulose-binding domain from endoglucanase CenC of *C. fimi* is the only protein known to bind soluble cellosaccharides and one of a small set of proteins which are known to bind any soluble polysaccharides. Also, listed in Tables 1 to 3 are examples of proteins containing putative β -1,3-glucan-binding domains (Table 1); proteins containing Streptococcal glucan-binding repeats (Cpl superfamily) (Table 2); and enzymes with chitin-binding domains, which may also bind cellulose (Table 3). The genes encoding each one of the peptides listed in Tables 1-4 are either isolated or can be isolated as further detailed hereinunder, and therefore, such peptides are expressible in plants. Scaffoldin proteins or portions thereof, which include a cellulose binding domain, such as that produced by *Clostridium cellulovorans* (Shoseyov *et al.*, PCT/US94/04132) can also be used as the cellulose binding peptide expressible in plants according to the present invention. Several fungi, including *Trichoderma* species and others, also produce polysaccharidases from which polysaccharide binding domains or proteins expressible in plants can be isolated. Additional examples can be found in, for example, Microbial Hydrolysis of Polysaccharides, R. A. J. Warren, Annu. Rev. Microbiol. 1996, 50:183-212; and "Advances in Microbial Physiology" R. K. Poole, Ed., 1995, Academic Press Limited, both are incorporated by reference as if fully set forth herein.

- New cellulose binding peptides with interesting binding characteristics and specificities can be identified and screened for and the

genes encoding same isolated using well known molecular biology approaches combined with a variety of other procedures including, for example, spectroscopic (titration) methods such as: NMR spectroscopy (Zhu *et al.* Biochemistry (1995) 34:13196-13202, Gehring *et al.* Biochemistry (1991) 30:5524-5531), UV difference spectroscopy (Belshaw *et al.* Eur. J. Biochem. (1993) 211:717-724), fluorescence (titration) spectroscopy (Miller *et al.* J. Biol. Chem. (1983) 258:13665-13672), UV or fluorescence stopped flow analysis (De Boeck *et al.* Eur. J. Biochem. (1985) 149:141-415), affinity methods such as affinity electrophoresis (Mimura *et al.* J. chromatography (1992) 597:345-350) or affinity chromatography on immobilized mono or oligosaccharides, precipitation or agglutination analysis including turbidimetric or nephelometric analysis (Knibbs *et al.* J. Biol. Chem. (1993) 14940-14947), competitive inhibition assays (with or without quantitative IC₅₀ determination) and various physical or physico-chemical methods including differential scanning or isothermal titration calorimetry (Sigurskjold *et al.* J. Biol. Chem. (1992) 267:8371-8376; Sigurskjold *et al.* Eur. J. Biol. (1994) 225:133-141) or comparative protein stability assays (melts) in the absence or presence of oligo saccharides using thermal CD or fluorescence spectroscopy.

The K_a for binding of the cellulose binding domains or proteins to cellulose is at least in the range of weak antibody-antigen extractions, i.e., $\geq 10^3$, preferably 10^4 , most preferably 10^6 M⁻¹. If the binding of the cellulose binding domain or protein to cellulose is exothermic or endothermic, then binding will increase or decrease, respectively, at lower temperatures, providing a means for temperature modulation of the binding step, see numeral 14 in Figure 1.

Thus, and as already stated, the phrase "polysaccharide binding peptide" includes an amino acid sequence which comprises at least a functional portion of a polysaccharide binding region (domain) of a polysaccharidase or a polysaccharide binding protein. The phrase further relates to a polypeptide screened for its cellulose binding activity out of a library, such as a peptide library or a DNA library (e.g., a cDNA library or a display library). By "functional portion" is intended an amino acid sequence which binds to cellulose.

The techniques used in isolating polysaccharidase genes, such as cellulase genes, and genes for cellulose binding proteins are known in the art, including synthesis, isolation from genomic DNA, preparation from cDNA, or combinations thereof. (See, U.S. Pat. Nos. 5,137,819; 5,202,247; 5,340,731; 5,496,934; and 5,837,814). The sequences for several binding domains, which bind to soluble oligosaccharides are known (See, Figure 1 of PCT/CA97/00033, WO 97/26358). The DNAs coding for a variety of polysaccharidases and polysaccharide binding proteins are also known. Various techniques for manipulation of genes are well known, and

include restriction, digestion, resection, ligation, *in vitro* mutagenesis, primer repair, employing linkers and adapters, and the like (see Sambrook *et al.*, Molecular Cloning - A Laboratory Manual, Cold Spring Harbor Laboratory, Cold Spring Harbor, New York, 1989, which is incorporated
5 herein by reference).

The amino acid sequence of a polysaccharidase can be used to design a probe to screen a cDNA or a genomic library prepared from mRNA or DNA from cells of interest as donor cells for a polysaccharidase gene or a polysaccharide binding protein gene. By using the polysaccharidase cDNA
10 or binding protein cDNA or a fragment thereof as a hybridization probe, structurally related genes found in other species can be easily cloned and provide a cellulose binding peptide which is expressible in plants according to the present invention. Particularly contemplated is the isolation of genes from organisms that express polysaccharidase activity using oligonucleotide
15 probes based on the nucleotide sequences of genes obtainable from an organism wherein the catalytic and binding domains of the polysaccharidase are discrete, although other polysaccharide binding proteins also can be used (see, for example, Shoseyov, *et al.*, Proc. Nat'l. Acad. Sci. (USA) (1992) 89:3483-3487).

Probes developed using consensus sequences for the binding domain of a polysaccharidase or polysaccharide-binding protein are of particular interest. The β -1,4-glycanases from *C. fimi* characterized to date are endoglucanases A, B, C and D (CenA, CenB, CenC and CenD, respectively), exocellobiohydrolases A and B (CbhA and CbhB,
25 respectively), and xylanases A and D (Cex and XylD, respectively) (see Wong *et al.* (1986) Gene, 44:315; Meinke *et al.* (1991) J. Bacteriol., 173:308; Coutinho *et al.*, (1991) Mol. Microbiol. 5:1221; Meinke *et al.*, (1993) Bacteriol., 175:1910; Meinke *et al.*, (1994) Mol. Microbiol., 12:413; Shen *et al.*, Biochem. J., in press; O'Neill *et al.*, (1986) Gene, 44:325; and
30 Millward-Sadler *et al.*, (1994) Mol. Microbiol., 11:375). All are modular proteins of varying degrees of complexity, but with two features in common: a catalytic domain (CD) and a cellulose-binding domain (CBD) which can function independently (see Millward-Sadler *et al.*, (1994) Mol. Microbiol., 11:375; Gilkes *et al.*, (1988) J. Biol. Chem., 263:10401; Meinke *et al.*, (1991) J. Bacteriol., 173:7126; and Coutinho *et al.*, (1992)
35 Mol. Microbiol., 6:1242). In four of the enzymes, CenB, CenD, CbhA and CbhB, fibronectin type III (Fn3) repeats separate the N-terminal CD from the C-terminal CBD. The CDs of the enzymes come from six of the

families of glycoside hydrolases (see Henrissat (1991) Biochem. J., 280:309; and Henrissat *et al.*, (1993) Biochem. J., 293:781); all of the enzymes have an N- or C-terminal CBD or CBDs (see Tomme *et al.*, Adv. Microb. Physiol., in press); CenC has tandem CBDs from family IV at its N-terminus; CenB and XylD each have a second, internal CBD from families III and II, respectively. Cex and XylD are clearly xylanases; however, Cex, but not XylD, has low activity on cellulose. Nonetheless, like several other bacterial xylanases (see Gilbert *et al.*, (1993) J. Gen. Microbiol., 139:187), they have CBDs. *C. fimi* probably produces other β -1,4-glycanases. Similar systems are produced by related bacteria (see Wilson (1992) Crit. Rev. Biotechnol., 12:45; and Hazlewood *et al.*, (1992) J. Appl. Bacteriol., 72:244). Unrelated bacteria also produce glycanases; *Clostridium thermocellum*, for example, produces twenty or more β -1,4-glycanases (see Beguin *et al.*, (1992) FEMS Microbiol. Lett., 100:523). The CBD derived from *C. fimi* endoglucanase C N1, is the only protein known to bind soluble cellosaccharides and one of a small set of proteins that are known to bind any soluble polysaccharides.

Examples of suitable binding domains are shown in Figure 1 of PCT/CA97/00033 (WO 97/26358), which presents an alignment of binding domains from various enzymes that bind to polysaccharides and identifies amino acid residues that are conserved among most or all of the enzymes. This information can be used to derive a suitable oligonucleotide probe using methods known to those of skill in the art. The probes can be considerably shorter than the entire sequence but should at least be 10, preferably at least 14, nucleotides in length. Longer oligonucleotides are useful, up to the full length of the gene, preferably no more than 500, more preferably no more than 250, nucleotides in length. RNA or DNA probes can be used. In use, the probes are typically labeled in a detectable manner, for example, with ^{32}P , ^3H , biotin, avidin or other detectable reagents, and are incubated with single-stranded DNA or RNA from the organism in which a gene is being sought. Hybridization is detected by means of the label after the unhybridized probe has been separated from the hybridized probe. The hybridized probe is typically immobilized on a solid matrix such as nitrocellulose paper. Hybridization techniques suitable for use with oligonucleotides are well known to those skilled in the art. Although probes are normally used with a detectable label that allows easy identification, unlabeled oligonucleotides are also useful, both as precursors of labeled probes and for use in methods that provide for direct detection of double-

stranded DNA (or DNA/RNA). Accordingly, the term "oligonucleotide probe" refers to both labeled and unlabeled forms.

Generally, the binding domains identified by probing nucleic acids from an organism of interest will show at least about 40 % identity (including as appropriate allowances for conservative substitutions, gaps for better alignment and the like) to the binding region or regions from which the probe was derived and will bind to a soluble β -1,4 glucan with a K_a of $\geq 10^3 \text{ M}^{-1}$. More preferably, the binding domains will be at least about 60 % identical, and most preferably at least about 70 % identical to the binding region used to derive the probe. The percentage of identity will be greater among those amino acids that are conserved among polysaccharidase binding domains. Analyses of amino acid sequence comparisons can be performed using programs in PC/Gene (IntelliGenetics, Inc.). PCLUSTAL can be used for multiple sequence alignment and generation of phylogenetic trees.

In order to isolate the polysaccharide binding protein or a polysaccharide binding domain from an enzyme or a cluster of enzymes that binds to a polysaccharide, several genetic approaches can be used. One method uses restriction enzymes to remove a portion of the gene that codes for portions of the protein other than the binding portion thereof. The remaining gene fragments are fused with expression control sequences to obtain a mutated gene that encodes a truncated protein. Another method involves the use of exonucleases such as *Bal31* to systematically delete nucleotides either externally from the 5' and the 3' ends of the DNA or internally from a restricted gap within the gene. These gene deletion methods result in a mutated gene encoding a shortened protein molecule which can then be evaluated for substrate or polysaccharide binding ability.

Any cellulose binding protein or cellulose binding domain may be used in the present invention. The term "cellulose binding protein" ("CBP") refers to any protein or polypeptide which specifically binds to cellulose. The cellulose binding protein may or may not have cellulose or cellulolytic activity. The term "cellulose binding domain" ("CBD") refers to any protein or polypeptide which is a region or portion of a larger protein, said region or portion binds specifically to cellulose. The cellulose binding domain (CBD) may be a part or portion of a cellulase, xylanase or other polysaccharidase, e.g., a chitinase, etc., a sugar binding protein such as maltose binding protein, or scaffoldin such as CbpA of *Clostridium celluovorans*, etc. Many cellulases and hemicellulases (e.g. xylanases and mannases) have the

ability to associate with cellulose. These enzymes typically have a catalytic domain containing the active site for substrate hydrolysis and a carbohydrate-binding domain or cellulose-binding domain for binding cellulose. The CBD may also be from a non-catalytic polysaccharide binding protein. To date, more than one hundred cellulose-binding domains (CBDs) have been classified into at least thirteen families designated I-XIII (Tomme *et al.* (1995) "Cellulose Binding Domains: Classification and Properties", in ACS Symposium Series 618 Enzymatic Degradation and Insoluble Carbohydrates, pp. 142-161, Saddler and Penner eds., American Chemical Society, Washington, D.C. (Tomme I) ; Tomme *et al.* Adv. Microb. Physiol. (1995) 37:1 (Tomme II); and Smant *et al.*, Proc. Natl. Acad. Sci U.S.A. (1998) 95:4906-4911, all of which are incorporated herein by reference). Any of the CBDs described in Tomme I or II or any variants thereof, any other presently known CBDs or any new CBDs which may be identified can be used in the present invention. As an illustrative, but in no way limiting example, the CBP or CBD can be from a bacterial, fungal, slime mold, or nematode protein or polypeptide. For a more particular illustrative example, the CBD is obtainable from *Clostridium cellulovorans*, *Clostridium cellulovorans*, or *Cellulomonas fimi* (e.g., CenA, CenB, CenD, Cex). In addition, the CBD may be selected from a phage display peptide or peptidomimetic library, random or otherwise, using e.g., cellulose as a screening agent. (See Smith Science (1985) 228:1315-1317 and Lam, Nature (1991) 354:82-84). Furthermore, the CBD may be derived by mutation of a portion of a protein or polypeptide which binds to a polysaccharide other than cellulose (or hemicellulose) but also binds cellulose, such as a chitinase, which specifically binds chitin, or a sugar binding protein such as maltose binding protein, rendering said portion capable of binding to cellulose. In any event, the CBD binds cellulose or hemicellulose. Shoseyov and Doi (Proc. Natl. Acad. Sci. USA (1990) 87:2192-2195) isolated a unique cellulose-binding protein (CbpA) from the cellulose "complex" of the cellulolytic bacterium *Clostridium cellulovorans*. This major subunit of the cellulose complex was found to bind to cellulose, but had no hydrolytic activity, and was essential for the degradation of crystalline cellulose. The CbpA gene has been cloned and sequenced (Shoseyov *et al.* Proc. Natl. Acad. Sci. USA (1992) 89:3483-3487). Using PCR primers flanking the cellulose-binding domain of CbpA, the latter was successfully cloned into an overexpression vector that enabled overproduction of the approximately 17 kDa CBD in *Escherichia coli*. The

recombinant CBD exhibits very strong affinity to cellulose and chitin (U.S. Pat. No. 5,496,934; Goldstein *et al.*, J. Bacteriol. (1993) 175:5762; PCT International Publication WO 94/24158, all are incorporated by reference as if fully set forth herein).

5 In recent years, several CBDs have been isolated from different sources. Most of these have been isolated from proteins that have separate catalytic, i.e., cellulose and cellulose binding domains, and only two have been isolated from proteins that have no apparent hydrolytic activity but possess cellulose-binding activity (Goldstein *et al.* J. Bacteriol. (1993)
10 175:5762-5768; Morag *et al.* Appl. (1995) Environ. Microbiol. 61:1980-1986).

Recombinant proteins:

Any protein for which a gene is known or can be isolated can be used as the recombinant protein and be fused to the cellulose binding peptide
15 according to the present invention. Advantageously, the recombinant protein is of a commercial value. A non-exhaustive list of recombinant proteins which can be manufactured utilizing the process of the present invention and their uses follows.

Thus, for example, glucoamylases and glucose isomerases are used
20 in the food processing industry to convert starch to high fructose corn syrup.

Another useful class of enzymes are proteinases, which are used for the hydrolysis of high molecular weight proteins and which are further used in combination with detergents in cleaning applications, in leather manufacturing processes, in the food industry, and in the manufacture of
25 alcoholic beverages.

Enzymes known as pectinesterases, and several related enzymes, are used for pectin hydrolysis in the food industry.

A class of enzymes known as lipases are used for the cleavage of ester linkages in triglycerides, and are used both in the food industry and for
30 effluent treatment.

The enzyme beta-galactosidase is used industrially for the hydrolysis of whey lactose.

An enzyme known as thermolysin is used in the production of the artificial sweetener aspartame.

35 An enzyme known as sulphydryl oxidase is used in the reduction of the cooked flavor of milk.

Enzymes known as catalases are used to remove hydrogen peroxides from milk, cheese, and egg processing, and are further used in the sterilization and oxidation of plastics and rubbers.

Heparinases are useful for the production of heparin and heparan sulfate oligosaccharides.

Other proteins, in addition to enzymes, are those which have affinities to other compounds. For example, bacteria, fungi, plants and animals all contain a large number of proteins that exhibit specific interactions with agents such as metal ions and toxic compounds, and have high affinities for such agents.

A class of proteins known as metalloproteins contain prosthetic groups that bind specifically to metal ions. An example of such a prosthetic group is the porphyrin group in hemoglobin. Some other examples of metal ion binding proteins include parvalbumin, which binds to calcium, and metallothionin, an animal protein that binds large amounts of metal ions, especially zinc. Such metal absorptive proteins could also be used for purification in industrial processes.

It is also envisioned that streams of flowing material could be degraded by microbial enzymes. It is known that certain pollutants, whether natural or synthetic, and certain pesticides and other durable organic compounds in the environment can be degraded (inactivated) or converted into useful compounds by microbial enzymes.

It is known, for example, that some microorganisms, for example *Pseudomonas putida*, possessed dehalogenases that are capable of degrading certain pesticides and herbicides, and rendering them less toxic. Similarly, hydrolysis of organophosphate insecticides have been observed by microbial enzymes.

It is also possible to produce antibodies within plant cells. The antibodies can include monoclonal antibodies or fragments thereof having at least a portion of an antigen binding region, including immunoactive entities such as Fv, F(abl)2, Fab fragments (Harlow and Lane, 1988 Antibody, Cold Spring Harbor), single chain antibodies (U.S. Pat. No. 4,946,778), chimeric or humanized antibodies (Morrison *et al.* Proc. Natl. Acad. Sci. USA (1984) 81:6851; Neuberger *et al.* Nature (1984) 312:604-608) and complementarily determining regions (CDR).

Another class of proteins are those that bind to antibodies, such as protein-A, protein-G, protein-L and their mutants.

It is also possible to produce protein antibiotics or peptides such as lysozyme or therapeutic proteins which might assist in healing processes, for example, certain wound healing peptides, growth factors and hormones. Proteins such as HSA can also be produced.

5 Another class of proteins include proteins such as agglutinin, zein, silk, elastine proteins as well as COMP, JUN, FOS and other proteins that may form stable protein-protein interactions such as coiled-coil interactions that may be useful for production of protein fibers.

Another example is the production of animal feed enzymes. Phytase
10 from *Aspergillus niger*, for example, increases the availability of phosphorus from feed for monogastric animals by releasing phosphate from the substrate phytic acid, therefore reducing the need for costly phosphorus supplements. A phytase cDNA was constitutively expressed in transgenic tobacco (*Nicotiana tabacum*) plants (Verwoerd *et al.*, Plant. Physiol.
15 (1995) 109:1199-205). Soybean plants transformed with a fungal phytase gene improve phosphorus availability whereas excretion was decreased for broilers. It appears that phytase can improve growth performance of broilers fed low phosphorous diets when provided either as a commercial supplement or in the form of transformed seeds (Denbow *et al.*, Poult. Sci.
20 (1989) 77:878-881).

Other recombinant proteins of interest, will for the most part be mammalian proteins, and will include blood proteins, such as serum albumin, Factor VII, Factor VIIc, Factor VIIvW, Factor IX, Factor X, tissue plasminogen factor, Protein C, von Willebrand factor, antithrombin
25 III, erythropoietin, colony stimulating factors, such as G-, M-, GM-, cytokines, such as interleukins 1-11, integrins, addressins, selectins, homing receptors, surface membrane proteins, such as surface membrane protein receptors, T cell receptor units, immunoglobulins (as further detailed above with respect to antibodies), soluble major histocompatibility complex
30 antigens, structural proteins, such as collagen, fibrin, elastin, tubulin, actin, and myosin, growth factor receptors, growth factors, growth hormone, cell cycle proteins, vaccines, fibrinogen, thrombin, cytokines and hyaluronidase. Additional examples include chymosin, polymerases, saccharidases, dehydrogenases, nucleases, oxido reductases such as fungal peroxidases and
35 lactases, xylanases, rennin, horse radish peroxidase, amylases and soil remediation enzymes.

The genes encoding all of the above listed proteins have been isolated and as such these proteins are readily available for recombinant

expression and production according to the teachings of the present invention. It will be appreciated that new genes encoding an ever growing spectrum of proteins are continuously discovered and isolated, rendering such genes available for molecular manipulation and recombinant expression. There is thus no intention to limit the recombinant protein produced utilizing the method of the present invention to any specific protein or list of proteins.

Cellulose binding peptide-recombinant protein fusions:

The fusion of two proteins for which genes has been isolated is well known and practiced in the art. Such fusion involves the joining together of heterologous nucleic acid sequences, in frame, such that translation thereof results in the generation of a fused protein product or a fusion proteins. Methods, such as the polymerase chain reaction (PCR), restriction, nuclease digestion, ligation, synthetic oligonucleotides synthesis and the like are typically employed in various combinations in the process of generating fusion gene constructs. One ordinarily skilled in the art can readily form such constructs for any pair or more of individual proteins. Interestingly, in most cases where such fusion or chimera proteins are produced, and in all cases where one of the proteins was a cellulose binding peptide, both the former and the latter retained their catalytic activity or function.

For example, Greenwood *et al.* (1989, FEBS Lett. 224:127-131) fused the cellulose binding region of *Cellulomonas fimi* endoglucanase to the enzyme alkaline phosphatase. The recombinant fusion protein retained both its phosphatase activity and the ability to bind to cellulose. For more descriptions of cellulose binding fusion proteins, see U.S. Patent No. 5,137,819 issued to Kilburn *et al.*, and U.S. Patent No. 5,719,044 issued to Shoseyov *et al.* both incorporated by reference herein. See also U.S. Pat. No. 5,474,925. All of which are incorporated herein by reference.

The recombinant protein immobilized via its fused counterpart to the cellulosic matter can be released from the plant derived cellulosic matter by cleavage thereof, e.g., by proteolysis, using either a nonspecific general protease such as proteinase K or trypsin, or a specific protease as further detailed hereinunder. For example, release can be effected by treatment with proteinase K at a concentration of about 50 µg/ml for about 20 minutes at about 37 °C (Din *et al.* Bio/Technology (1991) 9:1096-1099).

Inclusion of a dedicated cleavage site:

According to a preferred embodiment of the present invention the fusion protein includes the recombinant protein and the cellulose binding

peptide separated therebetween via a unique amino acid sequence recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein sequence.

As used herein in the specification and in the claims section that follows, the phrase "unique amino acid sequence recognizable and digestible by a protease" includes a protease recognition sequence which is both recognizable and readily accessible to a protease. Thus, the unique sequence can be a solitary sequence (i.e., which does not appear in the recombinant protein and optionally also not in the cellulose binding peptide) or alternatively, the sole sequence of several similar sequences which is not sequestered from the protease due to the tertiary structure of the recombinant protein and optionally the cellulose binding peptide. In both these cases proteolysis will release the recombinant protein from the fusion protein cellulosic matter complex.

As used herein in the specification and in the claims section that follows, the phrase "controllable intervening protein sequence" includes unique amino acid sequences capable of excision from or cleavage of a peptide under predetermined conditions in cis or in trans, e.g., increase in temperature, exposure to light, unblocking of amino acid residues by dephosphorylation and treatment with chemical reagents or deglycosylation, examples include proteolysis effected under acidic conditions (HCl, e.g., to cleave between Asp and Pro) and proteolysis effected by a proteolyzing reagent, such as CNBr to cleave downstream of Met, all as known in the art and/or as further described in U.S. Pat. No. 5,834,247, which is incorporated herein by reference.

Thus, according to an aspect of the present invention there is provided a composition of matter comprising (a) a plant derived cellulosic matter; and (b) a fusion protein including a recombinant protein and a cellulose binding peptide separated therebetween via a unique amino acid sequence recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein sequence, wherein the fusion protein is complexed to the plant derived cellulosic matter by affinity binding via the cellulose binding peptide.

Nucleic acid molecules which can be used according to preferred embodiments of the present invention to express the fusion protein in plant cells would therefore include a heterologous nucleic acid sequence including (i) a first sequence encoding a cellulose binding peptide; (ii) a second sequence encoding a recombinant protein, wherein the first and

second sequences are joined together in frame in either orientation; and (iii) a third sequence encoding a unique amino acid sequence recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein sequence, the third sequence is
5 between and in frame with the first and second sequences.

Thus, specific cleavage can be used to release the recombinant protein from the fusion protein cellulosic matter complex. For example, one can include a protease recognition site or a chemical cleavage site between the recombinant protein and the cellulose binding peptide. Examples of
10 recognition sites include those for collagenase, thrombin, enterokinase, and Factor X_a which are cleaved specifically by the respective enzymes. Chemical cleavage sites sensitive, for example, to low pH or cyanogen bromide, can also be used.

Where cleavage is used, the recombinant protein can be cleaved
15 readily from the cellulosic matter by the use of a protease specific for a sequence present therebetween and the cellulose binding peptide.

It will be appreciated in this respect that four main classes of specific proteases are known, including (i) cysteine proteases, including cathepsin B and L; (ii) aspartyl protease cathepsin D; (iii) serine proteases including
20 plasmin, tissue-type plasminogen activator (tPA) and urokinase-type plasminogen activator (uPA), and (iv) matrix metalloproteinases (MMPs), including collagenases, gelatinases A and B (MMP2 and MMP9) and stromelysin (MMP3). Members of these protease families are commercially available and their recognition sequences known. As such, these proteases
25 can be used to implement the step of releasing the recombinant protein from the plant derived cellulosic matter while implementing the process according to the present invention.

Genetically modified plant material:

According to an aspect of the present invention there is provided a
30 nucleic acid molecule comprising (a) a promoter sequence for directing protein expression in plant cells; and (b) a heterologous nucleic acid sequence as further detailed herein, wherein, the heterologous nucleic acid sequence is down stream the promoter sequence, such that expression of the heterologous nucleic acid sequence is effectable by the promoter sequence.
35 Such a nucleic acid molecule needs to be effectively introduced into plant cells, so as to genetically modify the plant.

There are various methods of introducing foreign genes into both monocotyledonous and dicotyledonous plants (Potrykus, I., Annu. Rev.

Plant. Physiol., Plant. Mol. Biol. (1991) 42:205-225; Shimamoto *et al.*, Nature (1989) 338:274-276). The principle methods of causing stable integration of exogenous DNA into plant genomic DNA include two main approaches:

- 5 (i) *Agrobacterium*-mediated gene transfer: Klee *et al.* (1987) Annu. Rev. Plant Physiol. 38:467-486; Klee and Rogers in Cell Culture and Somatic Cell Genetics of Plants, Vol. 6, Molecular Biology of Plant Nuclear Genes, eds. Schell, J., and Vasil, L. K., Academic Publishers, San Diego, Calif. (1989) p. 2-25; Gatenby, in Plant Biotechnology, eds. Kung,
10 S. and Arntzen, C. J., Butterworth Publishers, Boston, Mass. (1989) p. 93-112.

- (ii) direct DNA uptake: Paszkowski *et al.*, in Cell Culture and Somatic Cell Genetics of Plants, Vol. 6, Molecular Biology of Plant Nuclear Genes eds. Schell, J., and Vasil, L. K., Academic Publishers, San
15 Diego, Calif. (1989) p. 52-68; including methods for direct uptake of DNA into protoplasts, Toriyama, K. *et al.* (1988) Bio/Technology 6:1072-1074. DNA uptake induced by brief electric shock of plant cells: Zhang *et al.* Plant Cell Rep. (1988) 7:379-384. Fromm *et al.* Nature (1986) 319:791-793. DNA injection into plant cells or tissues by particle bombardment,
20 Klein *et al.* Bio/Technology (1988) 6:559-563; McCabe *et al.* Bio/Technology (1988) 6:923-926; Sanford, Physiol. Plant. (1990) 79:206-209; by the use of micropipette systems: Neuhaus *et al.*, Theor. Appl. Genet. (1987) 75:30-36; Neuhaus and Spangenberg, Physiol. Plant. (1990) 79:213-217; or by the direct incubation of DNA with germinating pollen,
25 DeWet *et al.* in Experimental Manipulation of Ovule Tissue, eds. Chapman, G. P. and Mantell, S. H. and Daniels, W. Longman, London, (1985) p. 197-209; and Ohta, Proc. Natl. Acad. Sci. USA (1986) 83:715-719.

- The *Agrobacterium* system includes the use of plasmid vectors that
30 contain defined DNA segments that integrate into the plant genomic DNA. Methods of inoculation of the plant tissue vary depending upon the plant species and the *Agrobacterium* delivery system. A widely used approach is the leaf disc procedure which can be performed with any tissue explant that provides a good source for initiation of whole plant differentiation. Horsch
35 *et al.* in Plant Molecular Biology Manual A5, Kluwer Academic Publishers, Dordrecht (1988) p. 1-9. The *Agrobacterium* system is especially viable in the creation of transgenic dicotyledenous plants.

There are various methods of direct DNA transfer into plant cells. In electroporation, the protoplasts are briefly exposed to a strong electric field. In microinjection, the DNA is mechanically injected directly into the cells using very small micropipettes. In microparticle bombardment, the DNA is adsorbed on microprojectiles such as magnesium sulfate crystals or tungsten particles, and the microprojectiles are physically accelerated into cells or plant tissues.

Following transformation plant propagation is exercised. The most common method of plant propagation is by seed. Regeneration by seed propagation, however, has the deficiency that due to heterozygosity there is a lack of uniformity in the crop, since seeds are produced by plants according to the genetic variances governed by Mendelian rules. Basically, each seed is genetically different and each will grow with its own specific traits. Therefore, it is preferred that the transgenic plant be produced such that the regenerated plant has the identical traits and characteristics of the parent transgenic plant, e.g., a reproduction of the fusion protein. Therefore, it is preferred that the transgenic plant be regenerated by micropropagation which provides a rapid, consistent reproduction of the transgenic plants.

Micropropagation is a process of growing new generation plants from a single piece of tissue that has been excised from a selected parent plant or cultivar. This process permits the mass reproduction of plants having the preferred tissue expressing the fusion protein. The new generation plants which are produced are genetically identical to, and have all of the characteristics of, the original plant. Micropropagation allows mass production of quality plant material in a short period of time and offers a rapid multiplication of selected cultivars in the preservation of the characteristics of the original transgenic or transformed plant. The advantages of cloning plants are the speed of plant multiplication and the quality and uniformity of plants produced.

Micropropagation is a multi-stage procedure that requires alteration of culture medium or growth conditions between stages. Thus, the micropropagation process involves four basic stages: Stage one, initial tissue culturing; stage two, tissue culture multiplication; stage three, differentiation and plant formation; and stage four, greenhouse culturing and hardening. During stage one, initial tissue culturing, the tissue culture is established and certified contaminant-free. During stage two, the initial tissue culture is multiplied until a sufficient number of tissue samples are

produced to meet production goals. During stage three, the tissue samples grown in stage two are divided and grown into individual plantlets. At stage four, the transgenic plantlets are transferred to a greenhouse for hardening where the plants' tolerance to light is gradually increased so that
5 it can be grown in the natural environment.

The basic bacterial/plant vector construct will preferably provide a broad host range prokaryote replication origin; a prokaryote selectable marker; and, for *Agrobacterium* transformations, T DNA sequences for *Agrobacterium*-mediated transfer to plant chromosomes. Where the
10 heterologous sequence is not readily amenable to detection, the construct will preferably also have a selectable marker gene suitable for determining if a plant cell has been transformed. A general review of suitable markers for the members of the grass family is found in Wilmink and Dons, Plant Mol. Biol. Repr. (1993) 11:165-185.

15 Sequences suitable for permitting integration of the heterologous sequence into the plant genome are also recommended. These might include transposon sequences and the like for homologous recombination as well as Ti sequences which permit random insertion of a heterologous expression cassette into a plant genome.

20 Suitable prokaryote selectable markers include resistance toward antibiotics such as ampicillin or tetracycline. Other DNA sequences encoding additional functions may also be present in the vector, as is known in the art.

The constructs of the subject invention will include an expression
25 cassette for expression of the fusion protein of interest. Usually, there will be only one expression cassette, although two or more are feasible. The recombinant expression cassette will contain in addition to the heterologous sequence one or more of the following sequence elements, a promoter region, plant 5' untranslated sequences, initiation codon depending upon
30 whether or not the structural gene comes equipped with one, and a transcription and translation termination sequence. Unique restriction enzyme sites at the 5' and 3' ends of the cassette allow for easy insertion into a pre-existing vector.

Viral infected plant material:

35 Viruses are a unique class of infectious agents whose distinctive features are their simple organization and their mechanism of replication. In fact, a complete viral particle, or virion, may be regarded mainly as a block of genetic material (either DNA or RNA) capable of autonomous

replication, surrounded by a protein coat and sometimes by an additional membranous envelope such as in the case of alpha viruses. The coat protects the virus from the environment and serves as a vehicle for transmission from one host cell to another.

5 Viruses that have been shown to be useful for the transformation of plant hosts include CaV, TMV and BV. Transformation of plants using plant viruses is described in U.S. Pat. No. 4,855,237 (BGV), EP-A 67,553 (TMV), Japanese Published Application No. 63-14693 (TMV), EPA 194,809 (BV), EPA 278,667 (BV); and Gluzman, Y. *et al.*,
10 Communications in Molecular Biology: Viral Vectors, Cold Spring Harbor Laboratory, New York, pp. 172-189 (1988). Pseudovirus particles for use in expressing foreign DNA in many hosts, including plants, is described in WO 87/06261.

Construction of plant RNA viruses for the introduction and
15 expression of non-viral foreign genes in plants is demonstrated by the above references as well as by Dawson, W. O. *et al.*, Virology (1989) 172:285-292; Takamatsu *et al.* EMBO J. (1987) 6:307-311; French *et al.* Science (1986) 231:1294-1297; and Takamatsu *et al.* FEBS Letters (1990) 269:73-76.

20 When the virus is a DNA virus, the constructions can be made to the virus itself. Alternatively, the virus can first be cloned into a bacterial plasmid for ease of constructing the desired viral vector with the foreign DNA. The virus can then be excised from the plasmid. If the virus is a DNA virus, a bacterial origin of replication can be attached to the viral
25 DNA, which is then replicated by the bacteria. Transcription and translation of this DNA will produce the coat protein which will encapsidate the viral DNA. If the virus is an RNA virus, the virus is generally cloned as a cDNA and inserted into a plasmid. The plasmid is then used to make all of the constructions. The RNA virus is then produced by transcribing the viral
30 sequence of the plasmid and translation of the viral genes to produce the coat protein(s) which encapsidate the viral RNA.

Construction of plant RNA viruses for the introduction and expression of non-viral foreign genes in plants is demonstrated by the above references as well as in U.S. Pat. No. 5,316,931

35 In one embodiment, a plant viral nucleic acid is provided in which the native coat protein coding sequence has been deleted from a viral nucleic acid, a non-native plant viral coat protein coding sequence and a non-native promoter, preferably the subgenomic promoter of the non-native

coat protein coding sequence, capable of expression in the plant host, packaging of the recombinant plant viral nucleic acid, and ensuring a systemic infection of the host by the recombinant plant viral nucleic acid, has been inserted. Alternatively, the coat protein gene may be inactivated
5 by insertion of the non-native nucleic acid sequence within it, such that a fusion protein is produced. The recombinant plant viral nucleic acid may contain one or more additional non-native subgenomic promoters. Each non-native subgenomic promoter is capable of transcribing or expressing adjacent genes or nucleic acid sequences in the plant host and incapable of
10 recombination with each other and with native subgenomic promoters. Non-native (foreign) nucleic acid sequences may be inserted adjacent the native plant viral subgenomic promoter or the native and a non-native plant viral subgenomic promoters if more than one nucleic acid sequence is included. The non-native nucleic acid sequences are transcribed or
15 expressed in the host plant under control of the subgenomic promoter to produce the desired products.

In a second embodiment, a recombinant plant viral nucleic acid is provided as in the first embodiment except that the native coat protein coding sequence is placed adjacent one of the non-native coat protein
20 subgenomic promoters instead of a non-native coat protein coding sequence.

In a third embodiment, a recombinant plant viral nucleic acid is provided in which the native coat protein gene is adjacent its subgenomic promoter and one or more non-native subgenomic promoters have been
25 inserted into the viral nucleic acid. The inserted non-native subgenomic promoters are capable of transcribing or expressing adjacent genes in a plant host and are incapable of recombination with each other and with native subgenomic promoters. Non-native nucleic acid sequences may be inserted adjacent the non-native subgenomic plant viral promoters such that
30 said sequences are transcribed or expressed in the host plant under control of the subgenomic promoters to produce the desired product.

In a fourth embodiment, a recombinant plant viral nucleic acid is provided as in the third embodiment except that the native coat protein coding sequence is replaced by a non-native coat protein coding sequence.

35 The viral vectors are encapsidated by the coat proteins encoded by the recombinant plant viral nucleic acid to produce a recombinant plant virus. The recombinant plant viral nucleic acid or recombinant plant virus is used to infect appropriate host plants. The recombinant plant viral

nucleic acid is capable of replication in the host, systemic spread in the host, and transcription or expression of foreign gene(s) in the host to produce the desired fusion protein.

Fusion protein compartmentalization - signal peptides:

5 As already mentioned hereinabove, compartmentalization of the fusion protein is an important feature of the present invention because it allows undisturbed plant growth. Thus, according to one aspect of the present invention, the fusion protein is compartmentalized within cells of the plant or cultured plant cells, so as to be sequestered from cell walls of
10 the cells of the plant or cultured plant cells.

The fusion protein can be compartmentalized within a cellular compartment, such as, for example, the cytoplasm, endoplasmic reticulum, golgi apparatus, oil bodies, starch bodies, chloroplastids, chloroplasts, chromoplastids, chromoplasts, vacuole, lysosomes, mitochondria or the
15 nucleus.

Accordingly, the heterologous sequence used while implementing the process according to this aspect of the present invention includes (i) a first sequence encoding a cellulose binding peptide; (ii) a second sequence encoding a recombinant protein, wherein the first and second sequences are
20 joined together in frame; and (iii) a third sequence encoding a signal peptide for directing a protein to a cellular compartment, the third sequence being upstream and in frame with the first and second sequences.

The following provides description of signal peptides which can be used to direct the fusion protein according to the present invention to
25 specific cell compartments.

It is well-known that signal peptides serve the function of translocation of produced protein across the endoplasmic reticulum membrane. Similarly, transmembrane segments halt translocation and provide anchoring of the protein to the plasma membrane, see, Johnson *et al.* The Plant Cell (1990) 2:525-532; Sauer *et al.* EMBO J. (1990) 9:3045-3050; Mueckler *et al.* Science (1985) 229:941-945. Mitochondrial, nuclear, chloroplast, or vacuolar signals target expressed protein correctly into the corresponding organelle through the secretory pathway, see, Von Heijne, Eur. J. Biochem. (1983) 133:17-21; Yon Heijne, J. Mol. Biol. (1986)
30 189:239-242; Iturriaga *et al.* The Plant Cell (1989) 1:381-390; McKnight *et al.*, Nucl. Acid Res. (1990) 18:4939-4943; Matsuoka and Nakamura, Proc. Natl. Acad. Sci. USA (1991) 88:834-838. A recent book by Cunningham and Porter (Recombinant proteins from plants, Eds. C. Cunningham and
35

A.J.R. Porter, 1998 Humana Press Totowa, N.J.) describe methods for the production of recombinant proteins in plants and methods for targeting the proteins to different compartments in the plant cell. In particular, two chapters therein (14 and 15) describe different methods to introduce
5 targeting sequences that results in accumulation of recombinant proteins in compartments such as ER, vacuole, plastid, nucleus and cytoplasm. The book by Cunningham and Porter is incorporated herein by reference. Presently, the preferred site of accumulation of the fusion protein according to the present invention is the ER using signal peptide such as Cel 1 or the
10 rice amylase signal peptide at the N-terminus and an ER retaining peptide (HDEL, SEQ ID NO:1; or KDEL, SEQ ID NO:2) at the C-terminus.

Promoters and control of expression:

Any promoter which can direct the expression of the fusion protein according to the present invention can be utilized to implement the process
15 of the instant invention, both constitutive and tissue specific promoters. According to presently preferred embodiment the promoter selected is constitutive, because such a promoter can direct the expression of higher levels of the fusion protein. In this respect the present invention offers a major advantage over the teachings of U.S. Pat. No. 5,474,925 in which
20 only tissue specific and weak promoters can be employed because of the deleterious effect of the fusion protein described therein on cell wall development. The reason for which the present invention can utilize strong and constitutive promoters relies in the compartmentalization and sequestering approach which prohibits contact between the expressed fusion
25 protein and the plant cell walls which such walls are developing.

Constitutive and tissue specific promoters, CaMV35S promoter (Odell *et al.* Nature (1985) 313:810-812) and ubiquitin promoter (Christensen and Quail, Transgenic research (1996) 5:213-218) are the most commonly used constitutive promoters in plant transformations and are the
30 preferred promoters of choice while implementing the present invention.

In corn, within the kernel, proteins under the ubiquitin promoters, are preferentially accumulated in the germ (Kusnadi *et al.*, Biotechnol. Bioeng. (1998) 60:44-52). The amylose-extender (Ae) gene encoding starch-branching enzyme IIb (SBEIIb) in maize is predominantly expressed in
35 endosperm and embryos during kernel development (Kim *et al.* Plant. Mol. Biol. (1998) 38:945-956). A starch branching enzyme (SBE) showed promoter activity after it was introduced into maize endosperm suspension cells by particle bombardment (Kim *et al.* Gene (1998) 216:233-243). In

transgenic wheat it has been shown that a native HMW-GS gene promoter can be used to obtain high levels of expression of seed storage and, potentially, other proteins in the endosperm (Blechl and Anderson, Nat. Biotechnol. (1996) 14:875-9). Polygalacturonase (PG) promoter was shown to confer high levels of ripening-specific gene expression in tomato (Nicholass *et al.* Plant. Mol. Biol. (1995) 28:423-435). The ACC oxidase promoter (Blume and Grierson, Plant. J. (1997) 12:731-746) represents a promoter from the ethylene pathway and shows increased expression during fruit ripening and senescence in tomato. The promoter for tomato 3-hydroxy-3-methylglutaryl coenzyme A reductase gene accumulates to high level during fruit ripening (Daraselia *et al.* Plant. Physiol. (1996) 112:727-733). Specific protein expression in potato tubers can be mediated by the patatin promoter (Sweetlove *et al.* Biochem. J. (1996) 320:487-492). Protein linked to a chloroplast transit peptide changed the protein content in transgenic soybean and canola seeds when expressed from a seed-specific promoter (Falco *et al.* Biotechnology (NY) (1995) 13:577-82). The seed specific bean phaseolin and soybean beta-conglycinin promoters are also suitable for the latter example (Keeler *et al.* Plant. Mol. Biol. (1997) 34:15-29). Promoters that are expressed in plastids are also suitable in conjunction with plastid transformation.

Each of these promoters can be used to implement the process according to the present invention.

Thus, the plant promoter employed can a constitutive promoter, a tissue specific promoter, an inducible promoter or a chimeric promoter.

Examples of constitutive plant promoters include, without being limited to, CaMV35S and CaMV19S promoters, FMV34S promoter, sugarcane bacilliform badnavirus promoter, CsVMV promoter, *Arabidopsis* ACT2/ACT8 actin promoter, *Arabidopsis* ubiquitin UBQ1 promoter, barley leaf thionin BTH6 promoter, and rice actin promoter.

Examples of tissue specific promoters include, without being limited to, bean phaseolin storage protein promoter, DLEC promoter, PHS β promoter, zein storage protein promoter, conglutin gamma promoter from soybean, AT2S1 gene promoter, ACT11 actin promoter from *Arabidopsis*, napA promoter from *Brassica napus* and potato patatin gene promoter.

The inducible promoter is a promoter induced by a specific stimuli such as stress conditions comprising, for example, light, temperature, chemicals, drought, high salinity, osmotic shock, oxidant conditions or in case of pathogenicity and include, without being limited to, the light-

inducible promoter derived from the pea *rbcS* gene, the promoter from the alfalfa *rbcS* gene, the promoters DRE, MYC and MYB active in drought; the promoters INT, INPS, *prxEa*, Ha *hsp17.7G4* and RD21 active in high salinity and osmotic stress, and the promoters *hsr303J* and *str246C* active in pathogenic stress.

Expression follow up:

Expression of the fusion protein can be monitored by a variety of methods. For example, ELISA or western blot analysis using antibodies specifically recognizing the recombinant protein or its cellulose binding peptide counterpart can be employed to qualitatively and/or quantitatively monitor the expression of the fusion protein in the plant. Alternatively, the fusion protein can be monitored by SDS-PAGE analysis using different staining techniques, such as, but not limited to, coomassie blue or silver staining. Other methods can be used to monitor the expression level of the RNA encoding for the fusion protein. Such methods include RNA hybridization methods, e.g., Northern blots and RNA dot blots.

Binding of the fusion protein to the plant derived cellulosic matter:

When sufficient expression has been detected, binding of the fusion protein to the plant derived cellulosic matter is effected. Such binding can be achieved, for example, as follows. Whole plants, plant derived tissue or cultured plant cells are homogenized by mechanical method in the presence or absence of a buffer, such as, but not limited to, PBS. The fusion protein is therefore given the opportunity to bind to the plant derived cellulosic matter. Buffers that may include salts and/or detergents at optimal concentrations may be used to wash non specific proteins from the cellulosic matter.

Extraction and purification:

In general, a recent book by Cunningham and Porter (Recombinant proteins from plants, Eds. C. Cunningham and A.J.R. Porter, 1998 Humana Press Totowa, N.J.) describes methods for the production of recombinant proteins in plants including methods for extraction of the proteins from the plants. The methods used herein for extraction of proteins from plants are similar, however the ability of the fusion protein to bind to cellulose dictates its fate, unless extraction is done under condition in which the cellulose binding peptide do not bind to cellulose, for example, pH higher than 10 (for most CBDs) or high concentration of glucose or cellobiose (200 mM or higher) for family IX CBDs. If the initial extraction is conducted under conditions that prevent binding, the supernatant is

cleared from the cellulosic matter and then the solution is brought by either dilution, dialysis or pH correction, if necessary, to a condition that enables binding, after which cellulose is added in a batch or the solution is loaded on a cellulose column. Cellulose affinity purification is conducted as described, for example, in U.S. Pat. Nos. 5,719,044; 5,670,623; 5,856,021; 5,137,819; 5,202,247; 5,340,731; and 5,474,925; and U.S. Pat. applications Nos. 08/788,621; and 08/788,622; EP 0 381 719 B1, and EP application No. 93907724.4. Alternatively, the extraction solution provides conditions that favor binding to the plant derived cellulosic matter.

In any case, while the fusion protein is bound to cellulose, further whases can be employed for further removal of unbound proteins, conditions which dissociate such binding or proteolytic cleavage can be used to isolate the fusion protein itself, or proteolytic cleavage can be used to isolate the recombinant protein, all as further detailed hereinabove.

Additional objects, advantages, and novel features of the present invention will become apparent to one ordinarily skilled in the art upon examination of the following examples, which is not intended to be limiting. Additionally, each of the various embodiments and aspects of the present invention as delineated hereinabove and as claimed in the claims section below finds experimental support in the following examples.

EXAMPLES

Reference is now made to the following examples, which together with the above descriptions, illustrate the invention in a non limiting fashion. Generally, the nomenclature used herein and the laboratory procedures in recombinant DNA technology described below are those well known and commonly employed in the art. Standard techniques are used for cloning, DNA and RNA isolation, amplification and purification. Generally enzymatic reactions involving DNA ligase, DNA polymerase, restriction endonucleases and the like are performed according to the manufacturers' specifications. These techniques and various other techniques are generally performed according to Sambrook *et al.*, molecular Cloning - A Laboratory Manual, Cold Spring Harbor Laboratory, Cold Spring Harbor, N.Y. (1989). Other general references are provided throughout this document. The procedures therein are believed to be well known in the art and are provided for the convenience of the reader. All the

information contained therein, as well as that contained in the Manual by Sambrook *et al.*, is incorporated herein by reference.

MATERIALS, CONSTRUCTS AND EXPERIMENTAL METHODS

5

Enzymes and Chemicals:

Chemicals were purchased from Sigma Israel Chemicals Ltd. (Rehovot, Israel) unless otherwise stated. Restriction enzymes were purchased from MBI Fermentas, Inc. (Amherst NY, USA) and Taq DNA polymerase was purchased from Promega Corp. (Madison, WI, USA).

10

Plasmids and Bacteria:

The ligation mixture of each cloning procedure was transformed into *E. coli* strain XL1-blue (Stratagene) competent cells. The bacteria were plated on LB-agar plates including 100 µg/ml ampicillin in the case of the pBlueScript and pUC plasmids, or 50 µg/ml kanamycin in the case of the shuttle vectors. Positive clones were verified by restriction analysis and sequencing.

15

Buffers and Media:

LB (Luria-Broth) - 1% bacto-tryptone, 0.5% yeast extract and 1% NaCl; PBS (Phosphate Buffered Saline) - 20 mM KH₂PO₄, 150 mM NaCl pH 7.2; PBS-T – PBS with 0.1% Tween 20.

20

Plant Materials and Growth Conditions:

Nicotiana tabaccum-SR1 (tobacco) plants were grown at 24-25 °C under a 16 h photoperiod, using cool-white fluorescent light (50-60 µE m⁻² S⁻¹).

25

Construction of ProtL-cex:

A vector containing the class-I patatin gene B33 promoter (Olesinski *et al.*, 1996, Plant Physiol. 111:541-550), fused to the cell1 signal sequence (Shani *et al.*, 1997, Plant Mol. Biol. 34:837-842), protein-L (hereinafter ProtL, Nilson *et al.*, 1993, J. Immunol. Meth. 164:33-40), CBD cex sequence (Gilkes *et al.*, 1991, Microbiol. Rev. 55:303-315) and HDEL (SEQ ID NO:1) retaining peptide sequence was constructed as follows.

30

A DNA fragment encoding the cell1 signal peptide (nucleotide 1-105 of SEQ ID NO:3) was generated by PCR using the following primers: No. 1 (BglII) 5'-AAAAAGATCTATGGCGCGAAAATCACTAA-3' (SEQ ID NO:4) and No. 2 (XbaI) 5'-AAAATCTAGATTTACGGAGAGCGTCGCG-3' (SEQ ID NO:5). A DNA fragment encoding the ProtL-CBDcex (nucleotides 3-1280 of SEQ ID NO:6) was generated by PCR using the

35

following primers: No. 3 (XbaI) 5'-AAAATCTAGAATGGCG GCGGTAGAAAATAAAG-3' (SEQ ID NO:7); and No. 4 (HDEL, Stop and SalI) 5'-AAAAGTCGACTTAAAGTTCATCATGCTCGACGCC GACCGTGCA-3' (SEQ ID NO:8). The two fragment were digested with
 5 BglII, XbaI and SalI and ligated in one step into pUC19 (New England Biolabs, Beverly, Massachusetts) that was pre digested with BamHI and SalI. The primer for the c-terminal end of the ProtL-CBD contained the retaining peptide sequence HDEL (SEQ ID NO:1) and a stop codon in frame. The DNA containing the Cell Signal-ProtL-CBD-HDEL
 10 (hereinafter, ProtL-CBD) fusion was excised using SmaI and SalI and was subcloned into the SmaI and SalI sites of the binary vector Bin19 (Bevan, 1984, Nuc. Acid Res. 12:8711-8721) under the class-I patatin gene B33 promoter (Olesinski *et al.*, 1996, Plant Physiol. 111:541-550).

Construction of ProtL-cexNG (Non-Glycosylated):

15 The non-glycosylated form of CBDcex (CBD Technologies Ltd.) was cloned into the Cell-ProtL-cex vector constructed as described above, thus replacing the CBDcex with CBDcexNG. Cloning was performed using the following PCR primers: Primer E, 5'-AAAACTAGTGCTAGCGG TCCAGCCGGC-3' (SEQ ID NO:9) which is a forward primer containing
 20 an *SpeI* restriction site and primer F, 5'-AAAAGTCGACTTA AAGTTCATCATGTCCAACGGTGCAAGGGGC-3' (SEQ ID NO:10) which is a reverse primer containing the ER retaining peptide sequence (HDEL), a stop codon and a *SalI* restriction site. The resultant 360 bp PCR product was digested with *SpeI* and *SalI* and ligated into Cell-ProtL-cex
 25 predigested with the same enzymes. Positive clones were sequenced for verification and designated pUC19-cell1-ProtL-cexNG-HDEL. Figure 2a shows the coding sequence (SEQ ID NO:11) and the encoded protein (SEQ ID NO:12) of construct pUC19-cell1-ProtL-cexNG-HDEL, which is schematically presented in Figure 2b.

30 ***Construction of the Shuttle Vector Containing a 35S- Ω Promoter:***

The Cell-ProtL-cexNG insert which was obtained by generated by digesting the pUC19-cell1-ProtL-cexNG-HDEL vector with *SmaI* and *SphI* (*PaeI*) was sub cloned into a Cd vector containing the CaMV 35S- Ω promoter. To ligate the Cell-ProtL-cexNG-HDEL insert, the Cd vector was
 35 digested with *SalI* and the overhang tail was blunted by a fill-in reaction using the Klenow fragment. The vector was then digested with *SphI*.

The resultant 35SΩ-cell1-ProtL-cexNG-HDEL vector and the pBI101 shuttle vector were digested via *Sma*I and *Sac*I and co-ligated to generate pBI-35SΩ-cell1-ProtL-cexNG-HDEL.

Construction of cex-Fx and Tma-Fx:

5 A CBDcex-Fx insert provided in a pBluescript II KS plasmid (pBS-cex-Fx) was obtained from Prof. Douglas Kilburn, Department of Microbiology and Immunology, Biotechnology Laboratory, The University of British Columbia, Vancouver. An ER retention peptide HDEL encoding sequence was ligated at the C-terminus of CBDcex-Fx as followed: Forward
10 primer 49, 5'-CTAGTCATGATGAACTTTAAGAGCT-3' (SEQ ID NO:13) and reverse primer 50, 5'-CTTAAAGTTCATCATGA-3' (SEQ ID NO:14) were mixed together at equi-molar ratios under denaturing conditions (94 ° C). The mixture was then allowed to cool to RT in order to allow annealing. The annealed primers were ligated into pBS-cex-Fx which was
15 predigested with *Spe*I and *Sac*I and the ligation mixture was used to transform XL1 blue competent cells. Positive clones were sequenced for verification and designated as pBS-cex-Fx-HDEL.

A Cell signal peptide encoding sequence was cloned into the N-terminus of pBS-cex-Fx-HDEL. The Cell signal peptide encoding
20 sequence was PCR amplified from pMH04 (Shani, Z., Dekel, M., Tsabary, G. and Shoseyov, O. (1997) Cloning and characterization of elongation specific endo-1,4-β-glucanase (cell) from *Arabidopsis thaliana*. Plant Molec. Biol. 34: 837-842.) using the following primers: Forward primer 51, 5'-AAAACCCGGGATGGCGCGAAAATC-3' (SEQ ID NO:15), containing
25 a *Sma*I restriction site, and reverse primer 52, 5'-AAAAGACGTCTTAC GGAGAGCGTCGCGGTAATC-3' (SEQ ID NO:16) containing an *Aat*II restriction site. The resulting 115 bp PCR product was digested with *Sma*I and *Aat*II and ligated into pBS-cex-Fx-HDEL. The ligation mixture was used to transform *E. coli* XL1 Blue competent cells. Positive clones were
30 verified via sequencing and designated as pBS-Sig-cex-Fx-HDEL. Figure 3a shows the coding sequence (SEQ ID NO:17) and the encoded protein (SEQ ID NO:18) of construct pBS-Sig-cex-Fx-HDEL, which is schematically presented in Figure 3b.

Replacing CBDcex with CBDTma:

35 CBDTma was PCR amplified from pET-CBDTma (Alam, M., Boraston, A.B., Kormos, J., Tomme, P. and Kilburn, D.G. Properties of the C-terminal family 9 cellulose-binding module of xylanase A from the hyperthermophilic bacterium *Thermotoga maritima*, Submitted) using

forward primer 53, 5'-AAAAGACGTCGGCTAGCGGAATAATGGTA
GCG-3', (SEQ ID NO:19), containing an *AatII* restriction site, and reverse
primer 54, 5'-AAAAACGCGTTGGGGATGGGGTCGGAC-3' (SEQ ID
NO:20), containing an *MluI* restriction site. The resultant 600 bp PCR
5 product was digested with *AatII* and *MluI* and ligated into pBS-Sig-cex-Fx-
HDEL that was predigested with the same enzymes. The ligation mixture
was used to transform *E.coli* XL1 Blue competent cells. Positive clones
were verified via sequencing and designated as pBS-Sig-Tma-Fx-HDEL.
Figure 4a shows the coding sequence (SEQ ID NO:21) and the encoded
10 protein (SEQ ID NO:22) of construct pBS-Sig-Tma-Fx-HDEL, which is
schematically presented in Figure 4b.

Shuttle Vector cloning:

A PJD-330 vector which contained the CaMV-35S- Ω promoter (a
kind donation from Prof. Gadi Galili, The Weizmann Institute, Rehovot,
15 Israel, Shaul, O. and Galili, G. (1992) Threonine overproduction in
transgenic tobacco plants expressing a mutant desensitized aspartate kinase
of *Escherichia coli*. Plant Physiol. 100: 1157-1163.) was digested with
HindIII and *SalI*. A 500 bp fragment was rescued and ligated into pBI101
(Clontech Laboratories Inc. Palo Alto, California, USA) predigested with
20 the same enzymes. The ligation mixture was used to transform *E.coli* XL1
Blue competent cells and verified positive clones were designated pBI-35S-
 Ω .

To clone CBDcex-Fx and CBDTma-Fx into the above described
shuttle vector, pBS-Sig-cex-Fx-HDEL and pBS-Sig-Tma-Fx-HDEL were
25 each digested with *SmaI* and *SacI* and respective 1.3 and 1.5 kb fragments
were rescued from these vectors and each ligated into pBI-35S- Ω
predigested with the same enzymes. The ligation mixture was used to
transform *E. coli* XL1 Blue competent cells and positive clones were
designated pBI-Sig-cex-Fx-HDEL and pBI-Sig-Tma-Fx-HDEL
30 respectively.

Plant Transformation:

The above described constructs were introduced into disarmed LB
4404 *Agrobacterium tumefaciens* by triparental mating (An, 1987, Meth.
Enzymol. 153: 292-305) and leaf-disc transformation was performed with
35 *Nicotiana tabacum*-SR1 plants as described previously (DeBlock et al.,
1984, EMBO J. 3:1681). Regenerated transgenic plants were selected on
kanamycin containing growth media and analyzed via PCR for the presence
of exogenic sequences as described below. Positive isolates were grown in

a tissue culture room or in a greenhouse and F₀ plants from independent transformation events were used for the protein purification assays.

Detection of Transgenic Plants by PCR from Chromosomal DNA:

DNA was extracted from leaves of *Nicotiana tabacum*-SR1 (tobacco) as described by Doyle and Doyle (1987, *Phytochem. Bull.* 19:11-15) and the ProtL-cex sequence PCR amplified from the transgenic plant DNA isolated using the following primers: Forward primer 1, 5'-AAAACCATGGCGGCGGTAGAAAATAAAG-3' (SEQ ID NO:23) and reverse primer 2, 5'-AAAAGGATCCCTTCTGGTTTTTCGTCAAC -3' (SEQ ID NO:24).

In a similar manner, cex-Fx and Tma-Fx sequences were also PCR amplified from transgenic plant DNA by using the following primers: Forward primer 3, 5'-AAAACCCGGGATGGCGCGAAAATC-3' (SEQ ID NO:25) and reverse primer 4, 5'-TGCGTTCCAGGGTCTGTTTCC-3' (SEQ ID NO:26). The PCR reaction mixture included 2.5 µl 10X Taq polymerase buffer (Promega, Madison, WI), dNTP mix (0.2 mM each nucleotide), 1.5 mM MgCl₂, 10 pmol of each primer, 1 unit Taq DNA polymerase (Promega, Madison, WI) and ddH₂O to a final volume of 25 µl. Mineral oil (25 µl) was added to the mixture to prevent evaporation during cycling. The PCR program included 35 cycles of: denaturation at 95 °C for 60 sec, annealing at 55 °C - 65 °C for 1 min and extension at 72 °C for 1-2 min. The resulting amplified fragment was purified from an agarose-TBE gel.

Purification of ProtL-cexNG:

As outlined in Figure 5, purification of ProtL-cex was conducted as follow: 0.5 gram of tobacco leaf was grounded in liquid nitrogen. The grounded material was resuspended in PBS-T containing 2 mM PMSF, 5 mM EDTA and 2 mM DTT and the mixture was incubated at 4 °C for 1 hour with inversion to allow binding of the ProtL-cex to the cell wall fraction. The mixture was centrifuged, and the supernatant and pellet recovered separately. The pellet was washed 3 times with PBS-T and the washes were combined to the supernatant fraction which was then reacted with 10 mg Avicel 200. The washed cellulose pellet was washed 3 more times with PBS-T. The pellet and supernatant fractions were each separated on SDS-PAGE, and immunoblotted using either anti CBDcex Ab or mouse IgG reagent grades primary antibodies and appropriate secondary antibodies conjugated to HRP.

Purification of CBDcex-Fx and CBDTma-Fx:

Purification of CBDcex-Fx and CBDTma-Fx was conducted as described above. Analysis of the resultant pellet and supernatant fractions was conducted using the anti-Fx, anti-CBDcex or anti-CBDTma primary antibodies and appropriate secondary antibodies conjugated to HRP.

EXPERIMENTAL RESULTS

Approximately 30 independent transgenic tobacco plants (F_0 , parental generation) were prepared from each of the ProtL-cex and Tma-Fx transformant lines. Confirmation of the presence of a transgene was conducted by kanamycin resistance and PCR analysis with specific primers as described above. The primers detected a 0.95 kb fragment in ProtL-transgenic plants (Figure 6), and 0.55 kb and 0.8 kb fragments from cex-Fx (Figures 7a-7b) and Tma-Fx transgenic plants (Figures 8a-b), respectively. In all cases, the binary vector was used as a positive control. Expression of the cellulose binding domain (CBD) in the ProtL-cex and Tma-Fx transgenic plants was confirmed via western blot analysis.

Detection and Purification of ProtL-cexNG:

Of the positive transformants identified via PCR amplification, four plants (1, 2, 5 and 15) expressed ProtL-CBD to a detectable level. The total protein from leaf tissue of transformed plants was extracted and allowed to bind to the cell wall cellulose. The unbound protein in the soluble fraction of the total protein was allowed to bind to exogenous cellulose as described in materials and methods. Western blot analysis of both fractions of the cell wall and the cellulose displayed a difference in the amount of ProtL-CBD present. ProtL-CBD was not detected in the cell wall fraction whereas in the cellulose fraction, a unique band was detected (Figure 9a). The detected ProtL-CBDcexNG was of a higher molecular weight (MW) as compared to the bacterial ProtL-cex which was used as a positive control. This may be due to glycosilation of the plant expressed protein. The ability of the ProtL-cexNG to bind cellulose and the ability of protein L to bind mouse IgG even following gel analysis (Figure 9b), confirmed that the two bi-functional fusion proteins are active. The anti-CBDcex as well as the mouse IgG western blots detected non-specific bands in the cell wall fraction. These non-specific bands appeared in the transgenic and wt plants, and represent a protein with a MW different than that expected for ProtL-cex.

By correlating the brightness of the signal specific band observed on the western blot with bands of ProtL-CBD isolated from *E.coli.*, the amount of ProtL-CBDcexNG accumulated in the transformed plant tissue was approximated to be 1 μ g fusion protein per gram of plant tissue.

5 ***Detection and Purification of cex-Fx:***

Cex-Fx transformants were examined for their ability to express cex-Fx. Two transformant lines (5 and 12) expressed the protein to a detectable level. CBDcex-Fx was detected in the cell wall and cellulose fractions (prepared as described above) in equal amounts (Figures 10a-b).
10 The amount of cex-Fx produced in the plant tissue was approximated at 5 μ g fusion protein per gram of plant tissue. As is evident from Figures 10a-b, the expressed fusion protein is of a higher MW then control CBDcex-Fxa which is expressed in mammalian cells. This shift in MW could be a result of inefficient processing of the protein, at the kex2 and Fx cleavage sites.

15 ***Detection and Purification of Tma-Fx:***

Tma-Fx transformants were examined for their ability to express Tma-Fx. Four transformants (11, 14, 17 and 19) expressed the protein to a detectable level. The expressed CBDTma-Fx was found only in the exogenous cellulose fraction (prepared as described above) indicating that
20 the CBDTma did not bind cell wall in the transformant plants (Figures 11a-d). This could be due to the high concentration of endogenous soluble sugars such as glucose, and cellobiose, which prevent the CBDTma from binding to the cellulose matrix. The soluble sugars in the supernatant fraction are diluted by the repeated washes and as such, the CBDTma
25 accumulated in this fraction is able to bind with exogenously added cellulose.

Further support for this theory can be found in the results of transformant 19 (Figures 11c-d). The amount of tissue recovered from this plant for extraction was significantly lower (4-10 times) then that recovered
30 from the other plants. Since the final volume of the samples was equal, the sugar concentration in the sample extracted from transformant 19 was lower, resulting in binding to the cell wall fraction.

The expressed fusion protein appeared to be of a higher MW then CBDcex-Fxa expressed in mammalian cells (positive control). This shift in
35 MW could be a result of inefficient processing of the protein, at the kex2 and Fx cleavage sites. The amount of Tma-fx accumulated in the transformant plant tissue was approximately 5 μ g of fusion protein per gram of plant tissue.

Thus, as clearly shown by the preceding examples, expression of and cell wall isolation of exogenous proteins in plant tissue can easily be facilitated by utilizing any of the cellulose binding peptides of the present invention.

5

Although the invention has been described in conjunction with specific embodiments thereof, it is evident that many alternatives, modifications and variations will be apparent to those skilled in the art. Accordingly, it is intended to embrace all such alternatives, modifications and variations that fall within the spirit and broad scope of the appended claims. All publications, patents and patent applications mentioned in this specification are herein incorporated in their entirety by reference into the specification, to the same extent as if each individual publication, patent or patent application was specifically and individually indicated to be incorporated herein by reference. In addition, citation or identification of any reference in this application shall not be construed as an admission that such reference is available as prior art to the present invention.

15

WHAT IS CLAIMED IS:

1. A process of expressing a recombinant protein in a plant and of isolating the recombinant protein from the plant, the process comprising the steps of:

- (a) providing a plant, a plant derived tissue or cultured plant cells expressing a fusion protein including the recombinant protein and a cellulose binding peptide being fused thereto, said fusion protein being compartmentalized within cells of said plant, plant derived tissue or cultured plant cells, so as to be sequestered from cell walls of said cells of said plant, plant derived tissue or cultured plant cells;
- (b) homogenizing said plant, plant derived tissue or cultured plant cells, so as to bring into contact said fusion protein with a plant derived cellulosic matter of said plant, plant derived tissue or cultured plant cells, to thereby effect affinity binding of said fusion protein via said cellulose binding peptide to said cellulosic matter, thereby obtaining a fusion protein cellulosic matter complex; and
- (c) isolating said fusion protein cellulosic matter complex.

2. The process of claim 1, further comprising the step of:

- (d) washing said fusion protein cellulosic matter complex, thereby removing endogenous plant proteins and other plant material therefrom.

3. The process of claim 2, further comprising the step of:

- (e) collecting said fusion protein cellulosic matter complex as a final product of the process.

4. The process of claim 2, further comprising the step of:

- (e) exposing said fusion protein cellulosic matter complex to conditions effective in dissociating said fusion protein from said cellulosic matter; and
- (f) isolating said fusion protein, thereby obtaining an isolated fusion protein.

5. The process of claim 4, wherein said conditions effective in dissociating said fusion protein from said cellulosic matter are selected from the group consisting of basic conditions, denaturative conditions and affinity displacement conditions.
6. The process of claim 4, further comprising the step of:
 - (g) exposing said isolated fusion protein to conditions effective in digesting said fusion protein so as to release said recombinant protein therefrom, thereby obtaining a released recombinant protein.
7. The process of claim 6, wherein said conditions effective in digesting said fusion protein so as to release said recombinant protein therefrom are selected from the group consisting of proteolysis effected via a protease and proteolysis effected under predetermined cis or trans conditions for digesting a controllable intervening protein sequence.
8. The process of claim 4, further comprising the step of:
 - (h) isolating said released recombinant protein.
9. The process of claim 2, further comprising the step of:
 - (e) exposing said fusion protein cellulosic matter complex to conditions effective in digesting said fusion protein so as to release said recombinant protein therefrom, thereby obtaining a released recombinant protein.
10. The process of claim 6, wherein said conditions effective in digesting said fusion protein so as to release said recombinant protein therefrom are selected from the group consisting of proteolysis effected via a protease and proteolysis effected under predetermined cis or trans conditions for digesting a controllable intervening protein sequence.
11. The process of claim 4, further comprising the step of:
 - (f) isolating said released recombinant protein.
12. A genetically modified or viral infected plant or cultured plant cells expressing a fusion protein including a recombinant protein and a cellulose binding peptide, said fusion protein being compartmentalized

within cells of said plant or cultured plant cells, so as to be sequestered from cell walls of said cells of said plant or cultured plant cells.

13. The genetically modified or viral infected plant or cultured plant cells of claim 12, wherein expression of said fusion protein is under a control of a constitutive or tissue specific plant promoter.

14. The genetically modified or viral infected plant or cultured plant cells of claim 12, wherein said fusion protein is compartmentalized within a cellular compartment selected from the group consisting of cytoplasm, endoplasmic reticulum, golgi apparatus, oil bodies, starch bodies, chloroplastids, chloroplasts, chromoplastids, chromoplasts, vacuole, lysosomes, mitochondria, and nucleus.

15. A genetically modified or viral infected plant or cultured plant cells expressing a fusion protein including a recombinant protein and a cellulose binding peptide separated therebetween via a unique amino acid sequence recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein sequence.

16. The genetically modified or viral infected plant or cultured plant cells of claim 15, wherein said fusion protein is compartmentalized within cells of said plant or cultured plant cells, so as to be sequestered from cell walls of said cells of said plant or cultured plant cells.

17. The genetically modified or viral infected plant or cultured plant cells of claim 15, wherein said fusion protein is compartmentalized within a cellular compartment selected from the group consisting of cytoplasm, endoplasmic reticulum, golgi apparatus, oil bodies, starch bodies, chloroplastids, chloroplasts, chromoplastids, chromoplasts, vacuole, lysosomes, mitochondria, and nucleus.

18. The genetically modified or viral infected plant or cultured plant cells of claim 15, wherein expression of said fusion protein is under a control of a constitutive or tissue specific plant promoter.

19. A composition of matter comprising:
- (a) a plant derived cellulosic matter of a plant; and
 - (b) a fusion protein including a recombinant protein and a cellulose binding peptide separated therebetween via a unique amino acid sequence recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein sequence, said fusion protein being expressed in said plant and complexed to said plant derived cellulosic matter of said plant by affinity binding via said cellulose binding peptide.
20. A nucleic acid molecule comprising:
- (a) a promoter sequence for directing protein expression in plant cells;
 - (b) a heterologous nucleic acid sequence including:
 - (i) a first sequence encoding a cellulose binding peptide;
 - (ii) a second sequence encoding a recombinant protein, wherein said first and second sequences are joined together in frame; and
 - (iii) a third sequence encoding a unique amino acid sequence being recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein sequence, said third sequence being between and in frame with said first and second sequences;

wherein, said heterologous nucleic acid sequence being down stream said promoter sequence, such that expression of said heterologous nucleic acid sequence is effectable by said promoter sequence.

21. The nucleic acid molecule of claim 20, further comprising a sequence element selected from the group consisting of an origin of replication for propagation in bacterial cells, at least one sequence element for integration into a plant's genome, a polyadenylation recognition sequence, a transcription termination signal, a sequence encoding a translation start site, a sequence encoding a translation stop site, plant RNA virus derived sequences, plant DNA virus derived sequences, tumor inducing (Ti) plasmid derived sequences, and a transposable element derived sequence.

22. A nucleic acid molecule comprising:
- (a) a promoter sequence for directing protein expression in plant cells;
 - (b) a heterologous nucleic acid sequence including:
 - (i) a first sequence encoding a cellulose binding peptide;
 - (ii) a second sequence encoding a recombinant protein, wherein said first and second sequences are joined together in frame; and
 - (iii) a third sequence encoding a signal peptide for directing a protein to a cellular compartment, said third sequence being upstream and in frame with said first and second sequences;

wherein, said heterologous nucleic acid sequence being down stream said promoter sequence, such that expression of said heterologous nucleic acid sequence is effectable by said promoter sequence.

23. The nucleic acid molecule of claim 22, wherein said heterologous nucleic acid sequence further includes

- (iv) a fourth sequence encoding a unique amino acid sequence being recognizable and digestible by a protease or under predetermined cis or trans conditions for digesting a controllable intervening protein sequence, said fourth sequence being between and in frame with said first and second sequences.

24. The nucleic acid molecule of claim 22, further comprising a sequence element selected from the group consisting of an origin of replication for propagation in bacterial cells, at least one sequence element for integration into a plant's genome, a polyadenylation recognition sequence, a transcription termination signal, a sequence encoding a translation start site, a sequence encoding a translation stop site, plant RNA virus derived sequences, plant DNA virus derived sequences, tumor inducing (Ti) plasmid derived sequences, and a transposable element derived sequence.

25. The nucleic acid molecule of claim 22, wherein said cellular compartment is selected from the group consisting of cytoplasm, endoplasmic reticulum, golgi apparatus, oil bodies, starch bodies,

chloroplastids, chloroplasts, chromoplastids, chromoplasts, vacuole, lysosomes, mitochondria, and nucleus.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/IL00/00330

A. CLASSIFICATION OF SUBJECT MATTER		
IPC(7) : Please See Extra Sheet.		
US CL : 435/69.1, 320.1, 410, 419, 468; 800/278, 287, 288, 295, 298		
According to International Patent Classification (IPC) or to both national classification and IPC		
B. FIELDS SEARCHED		
Minimum documentation searched (classification system followed by classification symbols)		
U.S. : 435/69.1, 320.1, 410, 419, 468; 800/278, 287, 288, 295, 298		
Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched		
Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)		
WEST, Agricola, Caplus, Biosis		
C. DOCUMENTS CONSIDERED TO BE RELEVANT		
Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	GODDIJN et al. Plants As Bioreactors. Trends In Biotechnology. September 1995, Vol. 13, pages 379-387, see whole document.	1-25
Y	GREENWOOD et al. Purification And Processing Of Cellulose-Binding Domain-Alkaline Phosphatase Fusion Proteins. Biotechnol. Bioeng. 1994, Vol. 44, No. 11, pages 1295-1305, especially pages 1296-1303.	1-25
Y	SEEBOTH et al. In-vitro Cleavage Of A Fusion Protein Bound To Cellulose Using The Soluble yscFs (Kex2) Variant. Appl. Microbiol. Biotech. 1992, Vol. 37, pages 621-625, especially pages 622-624.	1-25
<input checked="" type="checkbox"/> Further documents are listed in the continuation of Box C. <input type="checkbox"/> See patent family annex.		
* Special categories of cited documents:	*T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art *A* document member of the same patent family	
A document defining the general state of the art which is not considered to be of particular relevance		
E earlier document published on or after the international filing date		
L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)		
O document referring to an oral disclosure, use, exhibition or other means		
P document published prior to the international filing date but later than the priority date claimed		
Date of the actual completion of the international search	Date of mailing of the international search report	
19 OCTOBER 2000	28 NOV 2000	
Name and mailing address of the ISA/US Commissioner of Patents and Trademarks Box PCT Washington, D.C. 20231	Authorized officer <i>Ashwin Mehta</i> ASHWIN MEHTA	
Facsimile No. (703) 305-3230	Telephone No. (703) 308-0196
